## **ACKNOWLEDGEMENTS**

I want to express my appreciation to a number of people that have contributed in making this project an enjoyable and rewarding experience. Thank you to Dr. Michael Thomas, my research advisor, and to the other members of my committee, Professor Ranjan Roy, and Dr. Mike Lebow, for their support and encouragement. I would like to thank Andrew Cook and Brad Issac for their helpful comments and for allowing me to learn from their experiences. Thank you to my parents, Earl and Claudette, for their tremendous support and for always believing in me.

Above all, I would like to thank my dear wife, Debbie, for being my constant source of joy and delight, for being willing to do so much while I was so busy, and for being able to remember our goals and dreams that made making sacrifices easier.

### ABSTRACT

The operant conditioning model of pain behaviour and the cognitive-behavioral perspective of pain were evaluated in this study. This was accomplished by examining the relationships between beliefs, criticism and support of spouses and their persistent pain partner's beliefs, coping strategies, and adjustment. In addition, level of marital satisfaction was investigated. Two hundred middle aged, marital couples participated in this study. The pain subjects and spouses each completed a questionnaire package that included demographic and pain related questions, the West Haven-Yale Multidimensional Pain Inventory, the Survey of Pain Attitudes, the Coping Strategies Questionnaire, the Beck Depression Inventory, and the Marital Adjustment Test.

Results indicated that this study's sample differs greatly from chronic pain samples reported in the literature. Pain severity, pain interference, and negative mood were found in the non-clinical range. Spousal support and criticism were both found to be positively associated with the pain subject's reported level of pain interference. Spousal pain-specific beliefs were significantly associated with their pain partner's beliefs. The pain subject's disability belief was found to be positively associated with their reported levels of pain severity, pain interference, negative mood, and depressive symptoms. The pain sufferer's usage of coping strategies was found to be an unimportant factor in this study. Marital satisfaction was found to be positively associated with spousal support and negatively associated with spousal criticism. Couples who reported low marital satisfaction included a pain sufferer who reported higher pain severity, interference, and negative mood. Other results revealed many

other significant relationships between the spouse's belief, criticism and support and the pain subject's beliefs and adjustment.

For this sample, the cognitive-behavioral perspective of pain was found to be a more relevant model compared to the operant conditioning model of pain behaviour.

The significance of these findings and the implications for further research are discussed.

### INTRODUCTION

People who have persistent pain appear to report wide variability in their physical and psychological adjustment. Some people who have persistent pain seem to function and lead normal lives. These people seem to have adequate social supports, behavioral strategies, cognitive appraisals, and/or emotional stability to deal effectively with their pain. Others seem completely overwhelmed by their pain resulting in their pain becoming the primary focus of their lives. These people usually believe their pain will be permanently disabling and they may use maladaptive coping strategies to deal with their pain. Researchers are attempting to identify important variables that relate to these different outcomes in reaction to pain.

Pain has been conceptualized as a complex multidimensional phenomenon with bio-physiological, psychological and social components. Hence, it is becoming standard for pain patients who seek treatment to undergo a comprehensive assessment that evaluates not only the patient's medical findings, but also, the patient's coping strategies, psychological adjustment, and activity level (William & Keefe, 1991).

Also, pain-specific beliefs have been recognized as adding to the understanding of the pain experience. These beliefs have been shown to be associated with the pain patient's choice of coping strategies and level of adjustment (Jensen & Karoly, 1991). In addition, the social context in which the pain patient dwells is viewed as an important variable. For instance, Burman and Margolin (1992) conducted an extensive review evaluating the relationship between the marital relationship and health problems. From this review, they concluded that sufficient evidence is available to

strongly support the hypothesis that the patient's social context is a significant contributor to the patient's health or illness.

The purpose of this study was to investigate the relationships between the spouse's pain-specific beliefs, supportive and critical responses and the pain subject's pain-specific beliefs, coping strategies, and adjustment. First, this paper will review some of the literature related to pain and the marital relationship. Then a brief summary of research on pain-specific beliefs and coping strategies will be outlined. It will be hypothesized that the spouse's pain-specific beliefs, supportive and critical responses are important when attempting to understand the pain subject's pain-specific beliefs, coping strategies and adjustment. Also, marital satisfaction will be hypothesized as a significant variable to be considered in some of the above relationships.

# Marital Relationship

Some spouses and their pain partners reported added strain in their relationship due to the pain (Shanfield, Heiman, Cope, & Jones, 1979). For instance, couples tend to report more marital and sexual problems (Mohamed, Weisz, & Waring, 1978). Roy and Thomas (1989) found that chronic pain patients and their spouses both reported impairment of family functioning as compared to normal controls. Also, Ahern, Adams, and Folick (1985) evaluated low back pain patients and their spouses on emotional status, marital satisfaction, and functional impairment. They found that the spouses who were emotionally distressed also had chronic pain partners who were emotionally distressed and rated higher levels of functional impairment. In addition,

Kerns and Turk (1984) found that the spouses reported level of marital satisfaction and supportiveness was negatively related to depression in chronic pain partners. Finally, Mohamed et al. (1978) found that depressed chronic pain patients reported greater distress in their marital relationship as compared to depressed only patients.

Thus, for some couples, the presence of pain adds strain to the marriage relationship. Therefore, when one spouse experiences persistent pain, it seems likely that the couple will be vulnerable to marital difficulties. If marital distress is present, it may be reported by either the pain sufferer, the spouse, or both. Marital distress may be also related to family functioning, the couple's sexual relationship, and/or the couple's individual coping and psychological adjustment (Schwart, Slater, Birchler, & Atkinson, 1991). With two people interacting closely together, there is a strong likelihood that their negative behaviours and thoughts influence one another (Baucom & Epstein, 1990).

In contrast in the literature, Saarijarvi, Hyyppa, Lehtinen, and Alanen (1990) found that chronic pain patients and their spouses reported a high level of marital satisfaction as compared to a control group. Also, some researchers have suggested that pain can provide a stabilizing role in the family system (Jamison & Virtis, 1990). Rowat and Knafl (1985) found that over 50% of their sample of spouses of chronic pain subjects reported little or no distress regarding life and family due to their spouse's pain. In addition, these spouses held a positive outlook regarding their relationship, for example, saying that the pain had "brought [the couple] closer together". (p. 266) So, not all spouses and pain sufferers experience distress because

of the pain. Some spouses would seem to have the appropriate social supports, cognitive appraisals, and/or emotional stability to deal with the additional strain due to their spouse's pain (Subramanian, 1991). Furthermore, Payne and Norfleet (1986) reported that chronic pain sufferers reported adaptive adjustment to their pain when they had a supportive family environment and an emotionally stable spouse. Thus, this reported discrepancy in the literature may be due to variations in the spouse's beliefs and level of supportiveness towards the chronic pain subject. Additional research is needed to investigate if the marital relationship contributes to our understanding of the persistent pain sufferers beliefs, coping strategies, and level of adjustment.

# The Spouse's Behavior

The cognitive-behavioral perspective of pain suggests that the emotions, cognitions, and behaviour all play a role in the pain experience. For instance, this model of pain suggests that negative cognitions and the decline of activity are important variables when looking at the level of adjustment of pain sufferers (Goldberg, Kerns, & Rosenberg, 1993). In addition, the emotions, cognitions, and behaviour of the spouse may also add significantly to the understanding of pain (Baucom & Epstein, 1990). For example, Flor, Kerns, and Turk (1987b) found that spouses who were more supportive towards their pain spouses had pain spouses who reported lower activity levels. In comparison, they found that spouses who were more critical towards their pain spouses had spouses that reported higher activity levels. However, they commented that it was unclear whether the spouse's behaviour

determined the activity level, the activity level caused the spouse's behaviour or an extraneous variable influenced each of them. Nevertheless, it could be that the supportive or critical behaviours of the spouse reinforced or punished their partner's pain behaviours, respectively.

Gil, Keefe, Crisson, and Van Dalfsen (1987) examined the role that support from significant others played with regard to the perceived adjustment of the chronic pain patient. They found that patients who reported satisfaction with their support from others also reported higher levels of pain behaviour. In addition, Block, Kremer, and Gaylor (1980) found that patients that perceived their spouse as supportive were more likely to rate their pain higher when observed by their spouse that when observed by neutral observers. Flor, Kerns, and Turk (1987a) found that patients reported greater pain intensity and decreased activity levels when the patients perceived their spouse as supportive. Thus, these results suggested that supportive spousal responses towards their pain spouse can act to reinforce their spouse's pain behaviours, thus supporting Fordyce's (1976) operant conditioning model of pain behaviour.

However, Lousberg, Schmidt, and Groenman (1992) reported that the spouse's perception of being supportive towards the patient, but not the patient's perception of having a supportive spouse, was associated with greater pain and less activity reported by the patient. These results are difficult to interpret. It may be that the patients' perception were influenced by their level of pain or disability thus making their spouse's perception closer to reality. That is, the spousal reports would be more germane because the patients may have reported having a less supportive spouse

because of their level of discomfort. However, this finding does create confusion when trying to understand it in relation to the operant conditioning model of pain behaviour. If the patients did not perceive their spouse as being supportive, it is questionable whether the pain patient's behaviours were being reinforced. Thus, it seems important to examine both the spouse and the pain subject's perception of specific variables to further our understanding into these apparent discrepancies.

In contrast to the operant conditioning model of pain behaviour, Manne and Zautra (1989) found that spousal criticism was related to their partner's use of maladaptive coping strategies and poor psychological adjustment to pain (Manne & Zautra, 1990). In addition, they found that spousal support was related to their partner's usage of adaptive coping strategies and good psychological adjustment to pain. Goldberg et al. (1993) examined the relationship between spousal supportiveness of chronic pain patients and the level of activity and depression of the patient. They found that patients with highly supportive spouses reported less depression than patients with non-supportive spouses but this relationship was a function of the level of activity reported by the patient. That is, patients who reported low activity were greatly impacted by the level of spousal supportiveness where as patients who reported high activity levels were less influenced by spousal support. Thus, the literature is unclear as to whether a supporting spouse is an uniformly helpful or unhelpful response towards the pain subject.

Overall, the literature seems to support Fordyce's (1976) operant conditioning model of pain but a few studies have reported the opposite relationship between

spousal behaviours and adjustment of the pain subject. This discrepancy becomes clearer in light of Flor, Turk, and Rudy's (1989) study. They investigated the operant conditioning model of pain with married couples. Their results indicated that there was a positive relationship between pain impact (i.e., where higher scores were related to greater pain severity and pain interference) and spousal support for male patients but was only found in female patients when they perceived the marriage as satisfactory. The relationship did not hold when evaluating all the female patients or when the marital relationship was perceived as not satisfactory by the patient. Thus, the patient's level of marital satisfaction and gender played a significant role in the relationship between pain impact and spousal support. So, it seems possible that in the studies supporting operant conditioning reviewed above, the marital relationships were satisfactory thus resulting in these consistent findings. However, no data on marital relationships were obtained so this conclusion is speculative. Possibly other variables as well may have influenced this relationship.

# Spouse's Pain-Specific Beliefs

An important question that needs to be addressed is: are the spouse's pain-specific beliefs important in our understanding of the pain sufferer's beliefs, coping strategies, and level of adjustment? From a cognitive-behavioral perspective of pain, it is suggested that the cognitions of the spouse influence his or her spouse's cognitions and behaviour (Baucom & Epstein, 1990). One of the few studies that assessed cognitive and emotional factors of the spouse was Block and Boyer (1984). They found that spouse's positive cognitive appraisals of their spouse's pain was related to

their spouse's emotional adjustment and marital satisfaction. In addition, spouse's beliefs about pain may also be related to the pain sufferer's beliefs about the pain, usage of coping strategies and adjustment (Goldberg et al., 1993). Thus, it seems that the spousal relationship may play a key role in the pain sufferers adaptation to pain (Manne & Zautra, 1989).

Pain-specific beliefs of the spouses have received minimal attention. In one study assessing the spouses, Rowat and Knafl (1985) conducted a detailed investigation of spousal responses and cognitions related to their spouse's pain. Spousal behaviours, attitudes, beliefs, perceptions, knowledge, coping strategies, expectations, and history were assessed with the usage of open-ended questions in a semi-structured interview. They found that 60% of the spouses reported beliefs that their spouse's pain was permanent and unchangeable. Seventy-seven percent of the spouses reported that they were experiencing some form of emotional or social disturbance due to their partner's pain. Forty percent of the spouses reported having beliefs that there was nothing they could do to change their partner's pain experience. Questions examining if these spouses' pain-specific beliefs related to their partner's level of adjustment to the pain remain unanswered. Unfortunately, no correlations were conducted between spousal beliefs and their pain spouse's adjustment. Examining this relationship may have revealed important beliefs that related to their partner's level of adjustment.

# Pain-Specific Beliefs and Adjustment

In the last 10 years, researchers have shown a growing interest in the study of pain-specific beliefs and pain coping strategies of pain subjects and how these

variables relate to their level of adjustment (Keefe & Williams, 1990). Beliefs about pain can be defined as one's understanding of the pain in relation to himself or herself. Some examples of pain subjects' beliefs could be their appraisal of: (a) their control over their pain, (b) the degree that they think they are disabled, (c) their expectancies with regards to medication, family, and doctors, and (d) their perception of importance of psychological well-being. Such beliefs may hinder or facilitate a pain subject's ability to adapt to his or her pain. For example, Williams and Thorn (1989) examined the relationship between chronic pain patients beliefs and their reports of adjustment. They observed that the chronic pain patients who reported having the belief that their pain will be enduring also reported greater pain intensity.

In addition, Affleck, Tennen, Pfeiffer, and Fifield (1987) assessed beliefs, mood, and adjustment of rheumatoid arthritis patients. They found that patients who reported greater personal control over their medical care and treatment also reported positive mood and psychosocial adjustment. Also, Shutty, DeGood, and Tuttle (1990) found that middle aged, chronic pain patients who had beliefs related to the potential helpfulness of their treatment, upon finishing their treatment, reported less pain intensity, increased physical activity, and higher treatment satisfaction than patients who did not hold the belief that the treatment would be helpful. Furthermore, Riley, Ahern, and Follick (1988) observed that patients who believed that their pain was severely disabling reported greater physical and psychological dysfunction than patients who did not hold this belief regardless of their reported pain severity. Keefe and Williams (1990) observed that patient's beliefs related to their control over their

pain was negatively associated with depression, but not a general measure of psychological distress.

Furthermore, Jensen and Karoly (1992) reported that patients who believed that their pain was disabling reported lower levels of activity and psychological well-being. Also, they found that patients who believed that family members should always be supportive of them due to their pain reported greater levels of psychological distress than those that did not have this belief. Williams and Thorn (1989) found that the beliefs that chronic pain patients held related to pain had an impact on their pain reports, psychological functioning, and treatment compliance. In addition, Jensen, Turner, and Romano (1992) found that patients who believed that they had control over their pain also reported greater psychosocial functioning and less depression than those patients who did not hold this belief. Lastly, Elliott, Trief, and Stein (1986) found that married chronic pain patients who reported having the belief of being in control of important circumstances in their lives also reported less marital stress, more use of negotiation, less selective ignoring, and less depression than those patients who did not hold this belief. Thus, there is strong evidence that patients' pain-specific beliefs are associated with their level of adjustment (Affleck et al., 1987).

# Pain-Specific Beliefs and Coping

Beliefs about their pain has been suggested to be associated with the selection of coping strategies used by chronic pain patients (Jensen & Karoly, 1991). For example, Jensen and Karoly (1991) reported that certain pain-specific beliefs were related to coping strategies. Moreover, Jensen and Karoly (1992) found that patients who had

beliefs regarding their ability to control their pain were more apt to use active rather than passive coping strategies. However, they found that patients who had beliefs related to the disabling features of their pain reported usage of more passive than active coping strategies. Also, Strong, Ashton, and Chant (1992) found that having beliefs regarding the ability to control pain were related to the usage of pain coping strategies that involved ignoring the pain. They also found that having beliefs that the pain is disabling and that the family should always act supportively were associated with the use of a maladaptive coping strategy. It is unclear as to whether these pain-specific beliefs indirectly related to adjustment by way of coping strategies or if beliefs directly related to adjustment independent of which coping strategies were used (Strong et al., 1992).

Williams and Keefe (1991) reported that patients who held beliefs that their pain was enduring and mysterious were less likely to use adaptive coping strategies and more likely to catastrophize over their pain experience than patients who did not hold these beliefs. Also, Elliott et al. (1986) found that married chronic pain patients who reported having the belief of being in control of important circumstances in their lives also reported using more adaptive coping strategies to deal with stress. It is unclear from this study whether pain-specific beliefs or coping strategies are more important when examining adjustment (Lazarus & Folkman, 1984).

Regardless, it seems clear that certain pain-specific beliefs are associated with certain pain coping strategies. Certainly, cognitive appraisals are important factors in the selection of coping strategies but research is still needed to understand the pain

sufferer's social context which may be related to his or her cognitions about pain (Zautra & Manne, 1992).

# Coping Strategies and Adjustment

Keefe and his colleagues found that the usage of different coping strategies had different outcomes for psychological and physical adjustment. Rosenstiel and Keefe (1983) reported that high scores on a maladaptive coping strategy were related to high anxiety and depression. Also, they found that patients who used adaptive coping strategies reported greater activity level than those that did not use these strategies. Moreover, Turner and Clancy (1986) reported that high scores on a maladaptive coping strategy was related to higher scores of disability and psychosocial impairment. Jensen and Karoly (1991) found that chronic pain sufferers who used coping strategies that included either ignoring the pain, the use of positive self statements or the use of activities as a distraction reported less psychological distress than those that did not use these coping strategies. Also, Weickgenant, Slater, Patterson, Atkinson, Grant, and Garfin (1993) reported that depressed chronic low back pain patients reported greater use of maladaptive coping strategies than non-depressed patients. In addition, Jensen et al. (1992) found that catastrophizing and reinterpreting pain sensations coping strategies were related to psychosocial distress and depression. Also, they found that the usage of the pray and hoping coping strategy was related to poor physical functioning. Unfortunately, operational definitions of adaptive and maladaptive coping strategies are not consistent across the literature. Although coping strategies seem to play a role in the pain subject's reported level of adjustment, specific comparisons

between coping strategies are still needed.

In order to address some of the limitations of the literature previously reviewed, this study focused on middle aged, persistent pain sufferers, their spouses, and their perceptions and beliefs about pain. Much of the reviewed literature dealt with chronic pain patients as the research is sparse relating to persistent pain samples. Van Korff, Dworkin, and Le Resche (1990) conducted an epidemiological study in which they found 12% of their sample experienced chronic pain. A further 45% reported experiencing recurrent or persistent pain. Given the high prevalence, more research is needed to further understand persistent pain, as well as chronic pain.

Crook, Tunks, Rideout, and Browne (1986) investigated chronic pain patients from a Canadian specialty pain clinic and persistent pain subjects from community sample. They found that the chronic pain patients reported greater pain intensity and disability than the persistent pain subjects. Also, the persistent pain subjects reported less impairment of physical functioning and less psychosocial difficulties as compared to the pain patients. Notably, with a persistent sample, a smaller effect size was expected primarily caused by lower reported pain intensity. However, a persistent pain sample was still important to investigate for a number of reasons: (a) meaningful comparisons were made between persistent pain and chronic pain; (b) the persistent pain sample revealed adaptive and maladaptive pain-specific beliefs and coping strategies that may be useful knowledge for chronic pain patients; and (c) relationships were found in this persistent pain sample that had probably been missed in a chronic pain sample because of strong contaminating variables, such as, pain intensity,

depression, and level of disability.

## This Study's Objectives

The thrust of this study was to evaluate the relationships between spouses' pain-specific beliefs, supportive and critical responses with their pain partner's pain-specific beliefs, coping strategies, and level of adjustment. This study also investigated if the spouse's pain-specific beliefs were related to their level of supportiveness or criticalness. In addition, the pain subjects' beliefs and coping strategies were examined in relation to their reported level of adjustment.

### **Hypotheses**

The following hypotheses were investigated: (a) That the spouse's pain-specific beliefs are associated with the pain subject's pain-specific beliefs (Hypothesis 1); (b) That the spouse's pain-specific beliefs are associated with the pain subject's reported usage of cognitive coping strategies (Hypothesis 2); (c) That the spouse's pain-specific beliefs are associated with the pain subject's level of adjustment (Hypothesis 3); (d) That the spouse's pain-specific beliefs are associated with his or her responses towards the pain subject as reported by the pain subject and the spouse (Hypothesis 4); (e) That the spouse's and pain subject's reported response of the spouse are associated with the pain subject's level of adjustment when level of marital satisfaction is statistically controlled (Hypothesis 5); (f) That the spousal responses as reported by the pain subject and spouse are associated with the pain subject's usage of cognitive coping strategies (Hypothesis 6); (g) That the spousal responses as reported by the pain subject and spouse are associated to the pain subject's pain-specific beliefs

(Hypothesis 7); (h) That the pain subject's pain-specific beliefs are associated with the usage of cognitive coping strategies (Hypothesis 8); (i) That the pain subject's pain-specific beliefs are associated with level of adjustment (Hypothesis 9); (n) That the pain subject's usage of cognitive coping strategies are associated with level of adjustment (Hypothesis 10). Figure 1 shows the first four hypothesized relationships the were evaluated in this study. Figure 2 shows the fifth through to seventh hypothesized relationships the were evaluated in this study. Figure 3 shows the eighth through to tenth hypothesized relationships the were evaluated in this study.

### **METHOD**

### Subjects

Two hundred middle aged, non-clinical subjects reporting persistent pain and their spouses participated in this study. Persistent pain was defined as having pain for one or more episodes a week for three months or longer. One hundred and five (52.5%) persistent pain subjects were male. The average age of the pain subjects was 47 years old ( $\underline{SD} = 5$  years; Range = 34-67 years). The average age of the spouses was 48 years old ( $\underline{SD} = 5$  years; Range = 33 - 65). The couples reported having been married an average of 23 years ( $\underline{SD} = 5$  years; Range = 1 - 42 years). The pain subjects reported completing an average of 13 years ( $\underline{SD} = 3$  years; Range = 6 -21 years) of formal education and the spouses reported completing an average of 14 years ( $\underline{SD} = 3$  years; Range = 4 - 21 years).

Sixty-six percent of the pain subjects reported having a full time occupation, 19% reported working part time, 9% reported being a homemaker, 4% reported being on disability and 3% reported none of the above categories. Seven-three percent of the spouses reported having a full time occupation, 17% reported working part time, 7% reported being a homemaker, and 3% reported none of the above categories. The couples reported a median income between \$51-60,000. Ten percent of the pain subjects reported that they were receiving financial compensation due to their pain, 1% reported that the decision was pending regarding financial compensation, and 89% reported that they were not receiving any compensation. Seventy-one percent of the pain subjects had marital satisfaction ratings within the well adjusted range, whereas,

75% of the spouses had ratings within this range. Seventy-four percent of the couples had an average marital satisfaction rating within the well adjusted range.

### Measures

As a comprehensive exploratory evaluation, the pain subjects and their spouses completed a number of standardized questionnaires in a questionnaire package. Each questionnaire was shown to have good psychometric properties. In addition, important demographic and pain related questions were collected from both the pain subject and spouse (see Appendix A & B).

Adjustment was measured by a number of questionnaires. The concept of adjustment pertains to a multi-dimensional construct with psychological, physical and pain severity components (Jensen & Karoly, 1991). In this study, the following variables were used as measures of adjustment to pain: (a) pain severity, (b) depression, (c) negative mood, (d) activity level, (e) self control, and (f) pain interference (Jensen & Karoly, 1991; Jensen et al., 1992).

The West Haven-Yale Multidimensional Pain Inventory (WHYMPI) and the Spousal WHYMPI. The WHYMPI is a comprehensive self-report questionnaire that has demonstrated good internal reliability (alphas .70 to .90). Also, it has good test-retest reliability (r=.62 - .91) and good discriminant validity (Kerns et al., 1985). The WHYMPI consisted of three sections that measured a total of 12 scales. Section 1 measured five scales that pertained to the subject's perception of (a) the interference that the pain causes, (b) spousal support, (c) pain severity, (d) control over life (i.e., self control), (e) negative mood. Section 2 was comprised 3 scales developed from 14

spousal responses that are in reaction to the pain subject. The three scales were: (a) criticizing behaviours, (b) solicitous behaviours, and (c) distracting behaviours. In Section 3, there was a list of common activities that measured four subscales: (a) household chores, (b) outdoor activities, (c) social activities, and (d) activities away for home. In addition, a general measure of activity level was generated from these four scales by averaging the four subscale totals. All scales were evaluated on a seven point Likert scale with end point labelled accordingly. The Spousal WHYMPI was identical to the WHYMPI except that the spouses responded in regards to their appraisals of the their spouse's pain. Flor et al., (1987b) reported good internal reliability (alphas .63 to .92), and test-retest reliability (r = .76 to .95) for the spousal scale.

Survey of Pain Attitudes (SOPA(R)) and the Spousal SOPA(R). The SOPA(R) had 57 items assessing seven pain-specific beliefs (Jensen & Karoly, 1991). The scale assessed: (a) Control (belief that they were able to control their pain), (b) Disability (belief that they were permanently unable to function because of their pain), (c) Harm (belief that pain was equivalent to damaging themselves so they should avoid all exercise), (d) Emotional (belief that their emotions influenced their experience of pain), (e) Medication (belief that medications were appropriate treatment for chronic pain), (f) Solicitude (belief that family members, especially their spouses, should be supportive in response to their experience of pain), and (g) Medical Cure (belief that a medical cure will be found for their pain problem). All items were evaluated on the level of agreement of each item by using a five point Likert-like scale labelled: (0)

This is very untrue for me; (1) This is somewhat untrue for me; (2) This is neither true nor untrue for me (or it does not apply to me); (3) This is somewhat true for me; and (4) This is very true for me. In the original scale development sample, the internal reliabilities were adequate (alphas .42 to .71). The test-retest reliabilities was very good (r=.80 - .91) and all scales had criterion-oriented validity (Jensen et al., 1987; Jensen, 1991).

Coping Strategies Questionnaire (CSQ). The CSQ had 42 items representing seven pain coping strategies and two items that rated the pain subjects' ability to control pain and ability to decrease pain (Rosenstiel & Keefe, 1983). Each strategy was made up of six items and each rating scale had only one item. The coping strategies were: (a) diverting attention, (b) reinterpretation pain sensations, (c) coping self statements, (d) ignoring pain sensations, (e) praying and hoping, (f) catastrophizing, and (g) increasing activity level. Only the first five cognitive coping strategies were used in this study. In addition, a general measure of cognitive coping strategies was computed by averaging the first five coping strategies listed above.

Each item on the CSQ was rated on a seven-point scale. The labels were <u>never</u> (0), <u>sometimes</u> (3), and <u>always</u> (6). The control over pain and ability to decrease pain items were rated on a seven point scale ranging from <u>no control/cannot decrease it at all</u> (0) to <u>complete control/can decrease it completely</u> (6). Research has shown the Coping Strategies Questionnaire to be internally reliable (<u>r</u>=.72 to .89) and have good test-retest reliability (<u>r</u>=.54 at 10 weeks later and <u>r</u>=.58 at 26 weeks later) with a variety of pain populations (Crisson & Keefe, 1988; Keefe, 1992; Rosenstiel & Keefe,

1983; Turner & Clancy, 1986).

Beck Depression Inventory (BDI). The BDI was used as a measure of depressed mood for both the pain subjects and the spouse (Beck, Ward, Mendelson, Mock, & Erbaugh, 1961). The BDI is a 21 item questionnaire developed to assess the severity of depressive symptoms in adults. Answers were provided on a Likert-type scale for each section ranging from 0 to 3, indicating absence of the problem to extreme problem, respectively. Standard BDI screening suggested using cut-off scores of 13 for identifying subjects as depressed for research. Thus, subjects were labelled as non-depressed if they scored under 13 and subjects that scored 13 or above were labelled as depressed. Internal consistency (Cronbach's coefficient alpha) of .82 has been reported for the standard form. Test-retest reliability is very good ( $\mathbf{r} = 0.87$ ). Overall, the reliability ( $\mathbf{r} = 0.74$ ) and validity of this measure is very good (Beck et al., 1961; Rehm, 1976).

Locke-Wallace Marital Adjustment Test. The Locke-Wallace Marital Adjustment Test is a 15 items scale that measured the couple's perceived level of marital satisfaction (Locke & Wallace, 1959). Possible scores for this test ranged from 2 to 158. The first nine items were Likert-like items related to the couple's relationship compatibility. The last six items dealt with general relationship dynamics. They reported high reliability ( $\underline{r} = .90$ ) and adequate validity. Locke and Wallace (1959) were able to discriminate 96% of the well-adjusted couples and included only 17% of the maladjusted couples in their study by making the cut-off point at 100.

# **Procedure**

Introductory psychology students at the University of Manitoba were asked to solicit the participation of their parents in which one parent reported having persistent pain. During recruitment, each student received a request for participation form to bring home for their parents to sign (see Appendix C). When the students arrived at their designated time to complete their questionnaires, 90% brought the request for participation form that was signed by both parents. The students completed a questionnaire (see Appendix D) which was examined for exploratory purposes but was not included as part of this thesis. Two hundred and twenty-three students received two questionnaires to bring home to their parents. An information sheet containing a phone number that the parents could call if they have any questions about the study was included (see Appendix E). Only one parent called to ask for clarification regarding the criteria for participation in this study. In addition, the information sheet included asking for permission to phone the subjects if there was any clarification needed on their completed questionnaires. Eighty-seven percent of the subjects gave permission to be phoned if necessary.

Arrangements were made to collect the questionnaires after the parents had completed them. Eight couples did not complete the Locke-Wallace Marital Adjustment Test. Five common-law couples who completed the questionnaires were excluded from this study. Two hundred usable marital couple questionnaires were returned. This was a 90% return rate. This return rate is consistent with a similar study done at the University of Manitoba (Mogilevsky, 1993). All students received

experimental credits toward their introductory psychology course for the questionnaires that they return.

Both the students and their parents signed a volunteer consent form. This form explained that the questionnaire data will be kept strictly confidential and that they could withdraw from the project at any time. After their participation, all subjects read a debriefing sheet.

#### RESULTS

# Pain Related Questions

Forty-five percent of pain subjects reported that they were receiving treatment for their pain and fifty-two percent of them reported that they were taking medication for their pain. Pain subjects reported their pain duration to be on average 8 years (SD = 7 years and 10 months; Range = 3 months - 33 years). Eighty-seven percent of the pain subjects reported that they have not had surgery due to their pain, 10% reported having one surgery, and 4% reported having two or more surgeries. In addition, 18% of the pain subjects reported that they had attended a pain clinic in the past.

Table 1. Pain subjects reported pain sites (N=200).

Pain Site	Subjects <sup>a</sup> (%)	Females (%) <sup>b</sup>	Males (%) <sup>b</sup>
Back	94 (29.6)	38 (40.4)	56 (59.6)
Joints	70 (22.0)	35 (50.0)	35 (50.0)
Head	58 (18.2)	46 (79.3)	12 (20.7)
Muscle	36 (11.3)	21 (58.3)	15 (41.7)
Neck	31 (9.7)	17 (54.8)	14 (45.2)
Stomach	20 (6.3)	14 (70.0)	6 (30.0)
Chest	6 (1.9)	3 (50.0)	3 (50.0)
Tooth/Ear	3 (0.9)	1 (33.3)	2 (66.6)

<sup>&</sup>lt;sup>a</sup>Subjects column total to greater that 200 due to some subjects having multiple pain sites.

<sup>&</sup>lt;sup>b</sup>Females and Males percentages total to 100% for each pain site.

Fifty-eight percent of the pain subjects reported one pain site, 25% reported two pain sites, and 17% reported three or more pain sites. Table 1 shows the frequency of reported pain sites by the pain subjects.

# Hypothesis 1

Pain-specific beliefs reported by the pain subjects and their spouses were evaluated by calculating the means, standard deviations, and Cronbach's alpha coefficients (Cronbach, 1970; see Table 2). On average, the pain subjects and their spouses both reported that their strongest belief was that medications are an appropriate treatment for chronic pain. The pain subjects and the spouses both reported that their weakest belief was that the pain subjects are disabled or permanently unable to function because of their pain. Paired t-tests were conducted on the pain subjects and spousal beliefs using the Bonferroni approach for determining significance level. Only two of the beliefs were significantly different. One of the belief was that family members, especially the spouse, should be supportive in response to their experience of pain. Interestingly, this was a weak belief for pain subjects and a stronger belief for their spouse. The other was the belief that the pain subjects' emotions influenced their experience of pain. This was a weak belief for the

Hypothesis 1 stated that the spouse's pain-specific beliefs are associated with the pain subject's pain-specific beliefs. Table 3 shows correlations between the spouses' beliefs and the pain subjects' beliefs. For the same beliefs, correlations between the pain subjects and their spouse (i.e., the diagonal correlations) ranged between .27 and

.53. The weakest of these correlations was found to be the belief that family members, especially the spouses, should be supportive in response to their experience of pain. The strongest correlation was found to be the belief that medications are appropriate treatment for chronic pain.

Table 2. Means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' pain-specific beliefs and spouses' pain-specific beliefs (N = 200).

Next, simple regressions were conducted with each of the spouse's beliefs and the corresponding beliefs that were reported by the pain subject (see Table 4). The spouse's belief that medications are an appropriate treatment for chronic pain explained the greatest variance ( $\mathbb{R}^2 = 29\%$ ) of the pain subject's same belief. The spouse's belief that the pain subject is disabled or permanently unable to function because of the pain and the belief that the pain subject's emotions influenced the experience of pain each explained a moderate amount of the variance, ( $\mathbb{R}^2 = 26\%$  and  $\mathbb{R}^2 = 21\%$ , respectively) of the pain subject's same beliefs.

# Hypothesis 2

Table 5 shows the means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' cognitive coping strategies. The coping self statements was reported to be the most used coping strategy for pain, whereas, reinterpreting pain sensations was reported to be the least used coping strategy. Cronbach's coefficient alphas that generated a measure of internal reliability were found to range from .74 to .88.

Table 5. Means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' cognitive coping strategies (N = 200).

Average of Cognitive Coping Strategies	2.41	.85	.88	

ascale ranges from 0 to 6.

Hypothesis 2 stated that the spouse's pain-specific beliefs are associated with the pain subject's reported usage of cognitive coping strategies. Table 6 shows the correlations between the spouses' pain-specific beliefs and pain subjects cognitive coping strategies. The largest correlations were found between the praying and hoping coping strategy and the spouse's beliefs that medications are an appropriate treatment for chronic pain  $(\mathbf{r} = .23)$  and belief that a possible medical cure for the pain would be found in the future  $(\mathbf{r} = .32)$ .

\*p < .05. \*p < .01. \*\*\*\*p < .0001

Table 7 shows the multiple regressions for the spouses' beliefs and pain subjects' cognitive coping strategies. All the spouses' beliefs were entered into the multiple regression equations simultaneously. For each multiple regression analysis conducted in this study, the best model equation was determined by evaluating the coefficient of multiple determination,  $\mathbb{R}^2$ , for each of the variables in combination. The multiple regression analysis that explained the greatest amount of the variance ( $\mathbb{R}^2 = 16\%$ ) for a coping strategy included the spouse's beliefs that: (a) a medical cure will be found for the pain subject's pain problem, (b) medications are an appropriate treatment for

chronic pain, and (c) that the pain subject is able to control the pain, which predicted the praying and hoping coping strategy.

#### Hypothesis 3

Table 8 shows the means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' adjustment variables. Pain subjects rated their pain severity to be, on average, 2.57 on a scale ranging from 0 to 6. In addition, pain subjects rated their level of control to be, on average, 4.41 on the same scale range. Activity levels for the pain subjects ranged from 2.45 to 4.01.

Table 8. Means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' adjustment variables (N = 200).

Subscales	$\underline{\mathbf{M}}^{\mathtt{a}}$	<u>SD</u>	α

ascale ranges from 0 to 6.

Hypothesis 3 stated that the spouse's pain-specific beliefs are associated with the pain subject's level of adjustment. Table 9 shows the correlations between the spouses' beliefs and pain subjects' adjustment measures. The strongest association was between the spouse's belief that the pain subject is permanently unable to function because of the pain and the pain subject reported pain interference ( $\underline{r} = .57$ ). A moderate association was found between the spouse's belief that the pain subject is permanently unable to function because of the pain and the pain subjects reported pain severity ( $\underline{r} = .35$ ). Also, the association between the pain subject's reported negative mood and the spouse's belief that family members, especially the spouse, should be

supportive in response to their experience of pain was found to be moderate  $(\underline{r} = .28)$ .

Table 9. Correlations between the spouses' pain-specific beliefs and pain subjects' adjustment measures (N = 200).

Multiple regressions were conducted to evaluate the amount of explained variance accounted by the spouse's beliefs when examining the pain subjects' adjustment measures (see Table 10). The spouse's beliefs that the pain subject is permanently

unable to function because of their pain and that a medical cure will be found for their pain problem accounted for 35% of the variance when examining pain interference. In addition, the spouse's beliefs that the pain subject is permanently unable to function because of their pain and that pain is equivalent to damage so the pain subject should avoid all exercise explained 15% of the variance when examining pain severity.

Table 10. Multiple regressions for the spouses' pain-specific beliefs and pain subjects' adjustment measures (N = 200).

<u>Note.</u> Spouse's beliefs explained less than 5% of the variance of household activities, outdoor activities, activities away from home, social activities, and the average of the four activities, thus, are not reported.

p < .05. p < .01. p < .001. p < .001. p < .0001

Spouse's beliefs explained less than 5% of the variance of household activities, outdoor activities, activities away from home, social activities, and the average of the four activities, thus, are not reported.

### Hypothesis 4

Table 11 shows means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' perceived ratings of their spouse's responses towards them and the spouses' perceived ratings of their responses towards the pain subject. Paired t-tests were conducted using the Bonferroni approach for determining significance level.

Only one of the reported responses were significantly different. A significant difference was found for the usage of distracting responses by the spouse as perceived by the spouse and the pain subject. The pain subjects perceived less distracting

Table 11. Means, standard deviations, and Cronbach's alpha coefficients for the pain subjects' perceived ratings of their spouse's responses towards them and the spouses' perceived ratings of their responses towards the pain subject (N = 200).

<u>Note.</u> SUP=spousal support, SOL=perceived solicitous responses of spouse, DIST=perceived distracting responses of spouse, and CRIT=perceived critical responses of spouse.

<sup>\*</sup> $\underline{p}$  < .05. \*\* $\underline{p}$  < .01. \*\*\* $\underline{p}$  < .001. \*\*\*\* $\underline{p}$  < .0001

Furthermore, intercorrelations between the pain subjects' perceived rating of their spouse's responses towards them and the spouses' perceived ratings of their responses towards the pain subject revealed many significant results (see Table 13). Correlations were found to range from .38 to .50 on the spouse's responses rated by the spouses and pain subjects.

Hypothesis 4 stated that the spouse's pain-specific beliefs are associated with his or her responses towards the pain subject as reported by the pain subject and the spouse. Table 13 shows that many of the spouses' beliefs were associated with the perceived spousal responses. Interestingly, the spouses' critical responses were significantly associated to the spouses' belief that the pain subjects' emotions influenced their experience of pain ( $\underline{r} = .33$  when spouses' rated their own responses and  $\underline{r} = .22$  when pain subjects' rated their spouse's responses). In addition, the spouses' solicitous responses were significantly associated to the spouses' belief that medications are an appropriate treatment for chronic pain ( $\underline{r} = .34$  when spouses' rated their own responses and  $\underline{r} = .18$  when pain subjects' rated their spouse's responses). Also, the spouses' supportiveness was negatively associated to the spouses' belief that the pain subject can control the pain ( $\underline{r} = .24$  when spouses' rated their own responses and  $\underline{r} = .23$  when pain subjects' rated spouses's responses).

Table 13. Correlations between the spouses' perceived responses towards pain subjects, pain subjects' perceived responses of their spouse towards them and the spouses' pain-specific beliefs ( $\underline{N} = 200$ ).

Table 14 shows the multiple regressions for the spouses' perceived responses towards the pain subject, the pain subjects' perceived responses of their spouse towards them and the spouses' pain-specific beliefs. It is interesting to note that the spouses' belief that the pain subject is disabled and permanently unable to function because of the pain was retained in every model that examined the pain subjects' rating of their spouse's responses toward them. Also notable is that the spouse's beliefs that the pain subject is disabled and permanently unable to function because of

the pain and that medications are an appropriate treatment for chronic pain were retained in the models for spouses' ratings of their support and solicitous responses toward the pain subject. Critical responses were predicted by the belief that the pain subject's emotions influenced the experience of pain and the belief that family members, especially the spouse, should be supportive in response to their experience of pain, which accounted for 13% of the variance in the multiple regression.

#### Hypothesis 5

Table 5 shows the correlations between the perceived spousal responses as reported by the spouse and pain subject and the pain subject's adjustment measures. Interestingly, the pain subjects' reported level of self control was negatively associated to the pain subjects' rating of critical responses from their spouse ( $\underline{r} = -.33$ ). Notably, a moderate correlation was found between the pain subject's reported level of pain interference and the pain subject's ( $\underline{r} = .27$ ) and spouse's ( $\underline{r} = .30$ ) rating of supportiveness of the spouse. Also, a moderate correlation was found between the pain subject's reported negative mood and the pain subject's ( $\underline{r} = .28$ ) and spouse's ( $\underline{r} = .26$ ) rating of criticalness of the spouse. Marital satisfaction was significantly associated to all but one of the pain subject's adjustment measures. Although marital satisfaction was significantly associated with each of the pain subject's ratings, only one of the spouse's rating was significant.

Table 15. Correlations between the spouses' perceived responses towards pain subjects, pain subjects' perceived responses of their spouse towards them and the pain subjects' adjustment measures (N = 200).

Note. PS-Spousal Support=spousal support as rated by the pain subject, PS-Critical=perceived critical responses by spouse as rated by pain subject, and PS-Distracting=perceived distracting responses by spouse as rated by pain subject.

Hypothesis 5 stated that the spouse's and pain subject's reported spousal responses are associated with the pain subject's level of adjustment when level of marital satisfaction is statistically controlled. Table 16 shows the hierarchical regressions with the pain subjects' perceived responses of their spouse towards them and pain subjects' adjustment measures with marital satisfaction as a statistically controlled variable. As

marital satisfaction was a statistically controlled variable, it was entered into each regression first and retained regardless of its beta coefficient. Next, the other variables were entered into each regression equation simultaneously. Marital satisfaction was a significant predictor for all the pain subjects' adjustment measures except for the Beck depression inventory. The perceived critical responses by the spouse reported by the pain subjects was retained in all the regression analysis.

# Hypothesis 6

Hypothesis 6 stated that the spouse's behavior as reported by the pain subject and spouse are associated with the pain subject's usage of cognitive coping strategies. Table 17 shows the correlations between the spouses' perceived responses towards pain subjects, pain subjects' perceived responses of their spouse towards them and the pain subjects' cognitive coping strategies. The strongest correlation was found between the perceived solicitous responses as rated by the pain subject and the pain subject's usage of the praying and hoping coping strategy (r = .27). Table 18 shows the multiple regressions for the pain subjects' perceived responses of their spouse towards them and pain subjects' cognitive coping strategies. For each multiple regression, the spousal responses towards the pain subjects as reported by the pain subjects accounted for only a small portion of the variance of the coping strategies utilized by the pain subjects.

Table 17. Correlations between the spouses' perceived responses towards pain subjects, pain subjects' perceived responses of their spouse towards them and the pain subjects' cognitive coping strategies (N = 200).

#### Hypothesis 7

Hypothesis 7 stated that the spousal responses as reported by the pain subject and spouse are associated to the pain subject's pain-specific beliefs. A moderate correlation was found between the perceived critical responses from the spouse as reported by the pain subject and the pain subject's belief that family members, especially their spouse, should be supportive in response to their experience of pain (response to their experience of pain (response). Other moderate correlations were found between the perceived critical

responses from the spouse as reported by the pain subject and the pain subjects' belief that their emotions influenced their experience of pain ( $\underline{r} = .30$ ) and between the perceived solicitous responses from the spouse as reported by the pain subject and the pain subject's belief that medications are an appropriate treatment for chronic pain ( $\underline{r} = .30$ ).

Table 20 shows the multiple regressions with the pain subjects' perceived responses of their spouse towards them and pain subjects' pain-specific beliefs. In one

of the multiple regressions, the pain subjects' perceived spousal support and critical responses explained 10% of the variance of the pain subjects' belief that they are permanently unable to function because of their pain. In another regression analysis, the pain subjects' perceived critical responses by their spouse explained 16% of the variance of the pain subjects' belief that family members, especially their spouse, should be supportive in response to their experience of pain.

None of the pain subjects' perceived ratings of their spouses responses explained a significant amount of the variance of the pain subject's control belief.

## Hypothesis 8

Hypothesis 8 stated that the pain subject's pain-specific beliefs are associated with cognitive coping strategies. Table 21 shows the correlations between the pain subjects' pain-specific beliefs and cognitive coping strategies. Moderate correlations were found between the praying and hoping coping strategy and the beliefs that medications are an appropriate treatment for chronic pain ( $\mathbf{r} = .30$ ), that family members, especially their spouse, should be supportive in response to their experience of pain ( $\mathbf{r} = .36$ ), and that a medical cure will be found for their pain problem ( $\mathbf{r} = .37$ ). Other moderate correlations were found between the pain subjects' belief that they are permanently unable to function because of their pain and the cognitive coping strategies: coping self statements ( $\mathbf{r} = -.30$ ), ignoring pain sensations ( $\mathbf{r} = -.29$ ), and praying and hoping ( $\mathbf{r} = .27$ ).

Table 22 shows multiple regressions for the pain subjects' pain-specific beliefs and cognitive coping strategies. The pain subject's reported usage of the praying and hoping coping strategy was found to be predicted by the pain subjects' beliefs that a medical cure will be found for their pain problem, that family members, especially their spouse, should be supportive in response to their experience of pain, that they are permanently unable to function because of their pain, and that medications are an appropriate treatment for chronic pain, which accounted for 27% of the variance. Interestingly, the pain subject's belief that they are able to control their pain was retained in five of the six multiple regression models.

# Hypothesis 9

Hypothesis 9 stated that the pain subject's pain-specific beliefs are associated with level of adjustment. Table 23 shows correlations between the pain subjects' pain-specific beliefs and pain subjects' adjustment measures. Moderate correlations were found between the pain subjects' belief that they are permanently unable to function because of their pain and pain severity ( $\mathbf{r} = .38$ ), pain interference ( $\mathbf{r} = .64$ ), and negative mood ( $\mathbf{r} = .35$ ). Other moderate correlations were found between negative mood and the belief that family members, especially their spouse, should be supportive in response to their experience of pain ( $\mathbf{r} = .41$ ), between the pain subjects' belief that their emotions influenced their experience of pain and self control ( $\mathbf{r} = -.35$ ), and between the pain subjects' belief that pain is equivalent to damaging themselves so they should avoid all exercise and pain interference ( $\mathbf{r} = .40$ ).

Table 24 shows the multiple regressions for the pain subjects' pain-specific beliefs and adjustment measures. The pain subject's reported pain interference was found to be predicted by the pain subjects' beliefs that they are permanently unable to function because of their pain and that family members, especially their spouses, should be supportive in response to the pain, which accounted for 44% of the variance. In addition, the pain subject's reported negative mood was found to be predicted by the pain subjects' beliefs that they are permanently unable to function because of their pain, that their emotions influenced their experience of pain, and that family members, especially their spouse, should be supportive in response to the pain, which accounted for 28% of the variance.

# Hypothesis 10

Hypothesis 10 stated that the pain subject's usage of cognitive coping strategies are associated with level of adjustment. Table 25 shows correlations between the pain subjects' cognitive coping strategies and pain subjects' adjustment measures. Moderate correlations were found between the praying and hoping coping strategy and pain interference ( $\mathbf{r} = .30$ ), self control ( $\mathbf{r} = -.19$ ), and negative mood ( $\mathbf{r} = .22$ ). In addition, moderate correlations were found between the diverting attention coping strategy and pain interference ( $\mathbf{r} = .29$ ), negative mood ( $\mathbf{r} = .22$ ), and the Beck

depression scale (r = .20).

Table 25. Correlations between the pain subjects' cognitive coping strategies and pain subjects' adjustment measures (N = 200).

#### Post Hoc Analyses

Post hoc analysis were conducted to identify the most salient pain subject and spousal variables that predicted each of the pain subjects' beliefs, coping strategies, and measures of adjustment. First, Table 27 shows the multiple regressions predicting the pain subjects' pain-specific beliefs from the spousal and pain subjects' variables. The pain subject's belief that medications are an appropriate treatment for chronic pain was found to be predicted by the spouse's belief that medications are an appropriate treatment for pain, the pain subjects' reported usage of the ignoring pain coping strategy, the pain subjects' perceived solicitous responses by the spouse, and pain interference, which accounted for 40% of the variance. In addition, the pain subjects' belief that they are permanently unable to function because of their pain was found to be predicted by pain interference, the spouse's belief that the pain subject is permanently unable to function because of the pain, the pain subjects' reported usage of the coping self statements and praying and hoping coping strategies, which accounted for 52% of the variance.

Table 28 shows multiple regressions predicting the pain subjects' coping strategies from the spousal and pain subjects' variables. The pain subject's usage of the praying and hoping coping strategy was found to be predicted by the pain subject's beliefs that a medical cure will be found for their pain problem and that family members, especially their spouse, should be supportive in response to the pain, the pain subject's perceived solicitous responses by the spouse, and the spouse's beliefs that a medical cure will be found for their spouse's pain problem and that the pain subject is able to control the pain, which accounted for 34% of the variance.

Table 29 shows multiple regressions predicting the pain subjects' adjustment from the spousal and pain subjects' variables. One multiple regression revealed that the pain subject's reported pain interference was found to be predicted by the pain subject's belief that his or her pain is disabling, pain severity, negative mood and the spouse's belief that his or her partner's pain is disabling, which accounted for 68% of the variance. The pain subject's reported negative mood was found to be predicted by the pain subject's reported level of self control, pain interference, belief that family members, especially their spouse, should be supportive in response to the pain and the depression measure, which accounted for 54% of the variance.

Other post hoc analysis were conducted to examine whether pain duration, gender, known cause of pain, pain subject's level of depression, taking medication, presently being treated for pain, marital satisfaction and pain sites played significant roles in the hypothesized relationships. Appendix F shows the influence of pain duration on the hypothesized variables. Appendix G shows the influence of gender on the hypothesized variables. Appendix H shows the influence of whether the cause of the pain is known or not on the hypothesized variables. Appendix J shows the influence of whether the pain subject is taking medication or not on the hypothesized variables. Appendix K shows the influence of whether the pain subject is presently being treated or not on the hypothesized variables. Appendix L shows the influence of whether the pain subject is experiencing back pain or joint pain on the hypothesized variables. Appendix M shows the influence of whether the pain subject is experiencing head pain or joint pain on the hypothesized variables. Appendix N shows the influence of whether the pain subject is experiencing back pain or head pain on the hypothesized variables. Appendix O shows the influence of whether the couples reported high or low marital satisfaction on the hypothesized variables.

## DISCUSSION

This exploratory study investigated the relationships between the spouse's pain specific beliefs and responses toward the pain subject and the pain subject's painspecific beliefs, coping strategies, and level of adjustment. As expected, the selection procedures in this study produced a persistent pain sample different from the chronic pain samples that have been reported in the clinical literature. For instance, Flor et al. (1987b) found that chronic pain patients reported higher pain severity (M = 4.14), pain interference ( $\underline{M} = 4.26$ ), and negative mood ( $\underline{M} = 3.54$ ), and also lower control over life circumstances ( $\underline{M} = 3.71$ ) than what was found in this study. These differences suggest that conditions were not optimal to accurately evaluate an operant conditioning model of pain. That is, it appears that because the pain subjects were experiencing low to moderate levels of pain severity, they may not have exhibited high rates of pain behaviors. In addition, they may not have displayed a wide variety of pain behaviors. Thus, the reinforcement or punishment of infrequent pain behaviors may only minimally contribute to the maintenance of pain. In this case, the operant conditioning model of pain can not be adequately assessed as an appropriate model for persistent pain subjects who report low to moderate levels of pain severity.

For the operant conditioning model of pain to be supported by this study, pain severity and interference should have been positively associated with the spouse's supportive behavior and negatively associated with the spouse's critical responses. However, this study found that the pain subject's reported level of pain severity and interference were both positively associated with spousal support and critical

responses. It could be that the pain subjects with higher pain severity and interference elicited more spousal attention, which consisted of both supportive and critical responses. Possibly, the spouse's critical responses overshadowed their supportive behavior towards the pain subject. This speculation would be supported by Manne and Zautra's (1989) study. They reported that patients of a highly critical spouse reported poorer adjustment than patients who did not have critical spouses.

For the present study, the couples reported level of marital satisfaction was found to be a strong explanatory factor to our understanding of findings. The couples reported level of marital satisfaction was significantly associated with each of the pain subject's adjustment measures. Couples who reported low marital satisfaction included a pain subject who reported higher pain severity, high pain interference, lower control over life, higher negative mood, and more depressive symptoms. It seems that marital satisfaction may function as a moderating variable, thus, having an important role in the persistent pain subject's psychological adjustment. That is, if a couple report low levels of marital satisfaction, this may be a risk factor leading to the pain subject reporting greater psychological distress. This is consistent with previous research by Ahern et al. (1985) who found that marital maladjustment was significantly associated with a chronic pain patient's level of psychological distress.

Another important finding was that the spouses' solicitous responses were helpful behaviors and their critical responses were destructive behaviors that contributed to the couples perceived satisfaction of their marriage. That is, pain subjects who reported that their spouse responded solicitously also reported higher marital satisfaction. The

pain subjects who reported that their spouse responded critically also reported lower marital satisfaction. It is interesting to note that this association held when the spouse's perceived own critical responses towards the pain subject were evaluated. Furthermore, the spouses perceived their own responses were similar to the pain subjects. Not only was this found for critical responses, but also for supportive and solicitous responses. This finding may be explained by the high number of couples that reported adaptive marital relationships. Possibly the partners reported similar findings because they were not greatly stressed due to the low ratings of pain severity and interference, which may have resulted in their positive marital perspective.

A cognitive-behavioral perspective of pain was also evaluated in this study. This was done by evaluating the pain-specific beliefs of the couple that may have contributed to their evaluation and interpretation of the pain and its impact. Also, these beliefs were examined with respect to the pain subject's level of adjustment. First, the pain-specific beliefs of the spouse and the pain subject were evaluated and compared. It is interesting to note that the spouse's beliefs were all significantly associated with the corresponding beliefs of the pain subject. There are a number of explanations that could account for this finding. It could be that these couples communicated openly about the impact that pain has had on their lives. This is probable in light of the fact that 74% of the couples in this study reported adaptive marital relationships in spite of the presence of persistent pain for one member of the couple. Furthermore, it is possible that the pain subject's beliefs were interactive with the spouse's beliefs. For example, if a pain subject believed that his or her pain was

disabling, he or she may have acted disabled, thus, influencing his or her spouse's belief that the pain subject was disabled. Alternatively, the spouse's beliefs may have affected the pain subject's beliefs about the pain experience. That is, if the spouse thought his or her partner was disabled, the spouse may have been more likely to act in a way that may have encouraged the pain subject to feel like he or she was disabled.

Implications of this finding suggest that spouse's pain-specific beliefs have an important role when considering variables that are associated with the pain subject's beliefs. Ahern et al. (1985) reported that spouse's emotional distress was related to the pain patient's emotional distress. It could be that shared beliefs about the pain contributed to the couple's emotional distress. If couples have the same maladaptive beliefs about pain, then optimally, therapy for pain should focus on the couple and not just the pain sufferer. Marital therapy for pain couples would benefit from examining the pain-specific beliefs of both spouses to understand more fully these variables and their influence on each other.

One important variable that is consistently investigated in the pain literature is the level of pain interference. The pain subject's reported level of pain interference was found to be associated with the spouse's beliefs that the pain subject is permanently disabled and that a medical cure will be found for the pain. A possible explanation for this finding could be that the higher the level of pain interference, the more likely the injury or cause for the disability will be perceived as long term. In addition, these spouses may have believed strongly that a medical cure must be found in hopes that

their spouse would then be able to live a more active life. It seems intuitively reasonable to suggest that pain subjects that reported high pain interference contributed to their spouse's perception that they were physically disabled and in desperate need of a medical cure. For example, a pain subject who reported high pain interference may have constantly lamented about his or her pain and how limiting it is. Over a long period of time, this would create a situation where the spouse's beliefs would be highly influenced.

It seems that spouse's belief that his or her partner is disabled is important when investigating factors that contribute to the pain subject's disability belief. In addition, this spousal belief was also found to be significantly associated with each of the pain subject's measures of adjustment. That is, spouses that reported a strong that their partner was disabled had partners who reported higher pain severity, pain interference, lower control of life, higher negative mood and more depressive symptoms. Thus, it appears that this belief would be especially important to identify and attenuate when a couple participated in marital therapy.

The pain subject's beliefs were found to be highly associated with reported measures of pain severity, pain interference, negative mood, and depression. For instance, pain subjects who reported greater pain severity also held stronger beliefs that pain is equivalent to damaging themselves so they should avoid all exercise and that they are permanently unable to function because of their pain and, in addition, reported only a weak belief that they are able to control their pain. Pain subjects who reported higher pain interference, negative mood, and lower self control also held

stronger beliefs that they are permanently unable to function because of their pain and that family members, especially the spouse, should be supportive in response to their experience of pain. Pain subjects that reported a higher level of depression also held stronger beliefs that pain is equivalent to damaging themselves so they should avoid all exercise and that their emotions influence their experience of pain. The interrelationship among these findings are logically consistent with how a person would organize their specific beliefs about pain. These results clearly indicate that beliefs about pain at some point become a well organized and logically consistent belief system integrated into their personality as well as their behaviors. Such an integration of belief indicates that therapy targeted at changing behaviors will have to be accompanied by considerable changes in attitude.

Thus, from these findings, the pain subject's belief that he or she is able to control the pain was the only pain-specific belief that was associated with good psychological adjustment to pain. All of the other pain-specific beliefs seemed to have contributed to the pain subject's poor attitudes about their pain experience. An explanation for this finding is that all the pain specific beliefs (with the exception of the control belief) focuses on the negative aspects of the pain (such as, disabling, harmful, emotionally draining) or focuses on other people and things that may fail (such as, spouse, doctor, and medication). These negative cognitions are consistent with what Jensen, Turner, and Romano's (1994) study found. They reported that these above pain-specific beliefs were related to greater depression and greater physical dysfunction. These findings suggest that it would be very important for the pain

sufferer's treatment to include the identification and elimination of these negative beliefs before more adaptive beliefs and behaviors are suggested to the pain sufferer.

Overall, the findings in this study seem to have been better explained by a cognitive-behavioral perspective of pain. That is, it seems that the pain-specific beliefs of both the spouse and the pain subject were relatively more important to our understanding of the pain subject's reported level of adjustment. These beliefs contributed to both the spouse's and pain subject's evaluation and interpretation of the impact of the pain on themselves, each other, and their marital relationship.

Due to the low ratings of pain severity in this sample in comparison to a clinical sample, it seems that usage of coping strategies was not as important a factor in understanding the pain subject's level of adjustment. Generally, low correlations were found between the coping strategies and the other variables studied. This finding is consistent with other research that reported that coping strategies are of greater explanatory power when pain ratings are at a high level (Estlander & Harkapaa, 1989).

A number of limitations of this study need to be mentioned. First, the sample was acquired through the recruitment of students to solicit their parents. No validity checks were made as to the truthfulness of the parent's claims of having persistent pain. However, it is interesting to not that 98% of the usable questionnaires had either returned the request for participation form or had given permission to be called or both. This gives credibility to the assumption that the participants did fill out the questionnaire and responded consciously. This assumption of valid responding by the subjects was also supported by the high number of expected correlations. Another

limitation was that this sample may not be representative of all persistent pain sufferers for the following reasons: (a) the sample was acquired non-randomly, (b) some subjects were discarded from the study because they did not meet the study's criteria, and (c) not all questionnaires that were given to the students were returned. Thus, it is unknown what sample biases may have resulted due to the method of sample recruitment. Thus, generalization of these results must be made with caution. A third limitation was that this study was correlational in nature. Thus, no causal relationships can be verified.

Further research must continue to take into consideration these important spousal variables that significantly contribute to the pain subject's psychological and physical well-being. Also, future research should identify any gender differences that maybe present when the "well" spouse is male or female. Possibly, "well" female spouses are more supportive that "well" male spouses. Only with further research will this speculation be resolved. The marital relationship seemed to play an especially important role in the couple's evaluation and interpretation of the pain and its impact. Further research should be pursued to understand more fully these relationships. Possibly, a "health" marriage is an important component of the persistent pain sufferers good adjustment.

In addition, further investigation is needed on specific pain sites (i.e., headache pain, back pain, joint pain, etc.) to determine differences on the spousal variables of interest. Possibly, differences are present between a spouse of a headache sufferer and a spouse of a back or joint pain sufferer. Also, further investigation into adaptive and

maladaptive coping strategies is necessary. Until we gain a greater understanding as to which pain coping strategies are appropriate for pain sufferers, treatment for pain sufferers will be of limited value. Consistent usage of adaptive coping strategies could make the difference between a pain sufferer who is debilitate by the pain and a pain sufferer who is accommodating to the pain

## PERSISTENT PAIN RESEARCH QUESTIONNAIRE

TO BE FILLED OUT BY THE PARENT WHO HAS PERSISTENT PAIN

Persistent pain can be a depressing and limiting condition. Research is beginning to show that how people think about and cope with their pain plays a role in how people adjust with their pain. Also, the family is considered a key factor in the persistent pain person's life. Researchers in the Psychology Department at the University of Manitoba are trying to better understand which factors are related to adjustment. IF YOU HAVE PERSISTENT PAIN (PAIN ONE OR MORE TIMES A WEEK AT SAME LOCATION FOR THREE MONTHS OR LONGER) THEN YOU ARE ELIGIBLE TO PARTICIPATE IN THIS RESEARCH PROJECT.

I	hereby agree to take part in this
project on the understanding that t	he information I provide will be
kept strictly confidential and that	I can withdraw from this project
at any time.	

## PAIN RESEARCH QUESTIONNAIRE

	Code N	lo•	
1.	DATE OF BIRTH: DAY MONTH YEAR		
2.	Gender: a) Male b) Female		
3.	Marital Status: a) Single b) Married		
	c) Separated d) Divorced e) Widowed		
4.	If married, for how many years		
5.	Living: a) with spouse b) commonlaw c) separated		
	d) with parent(s) e) with friend(s) f) other		
6.	How many of your children are living with you presently?		
	0 1 2 3 4 5 6 7 8 9 10 11+		
7.	Please circle the number of children you have:		
	0 1 2 3 4 5 6 7 8 9 10 11+		
8.	Circle years of education completed:		
	1 2 3 4 5 6 7 8 9 10 11 12		
Co.	llege/University 1 2 3 4		
Gra	aduate School 1 2 3 4 5		
9.	Employment: a) full time b) part time c) homemaker		
	d) student e) retired f) unemployed g) on disability		
10.	. Are you receiving compensation?		
	a) yes, receiving financial compensation		
	b) decision regarding compensation pending		
	c) no, not receiving financial compensation		
10a	a. Are you presently being treated for your pain?	Yes	No

11.	. If married give your annual family income; if unmarried please
	estimate your annual income (approximately to the nearest thousand)
	Please circle the appropriate number
	(a) less then \$10,000 1
	(b) between \$11,000 and \$20,000 2
	(c) between \$21,000 and \$30,000 3
	(d) between \$31,000 and \$40,000 4
	(e) between \$41,000 and \$50,000 5
	(f) between \$51,000 and \$60,000 6
	(g) between \$61,000 and \$70,000 7
	(h) between \$71,000 and \$80,000 8
	(i) between \$81,000 and \$90,000 9
	(j) between \$91,000 and \$100,000 10
	(k) greater than \$100,000 11
	(1) unknown 12
13.	Please circle the location(s) of your persistent pain:
	1) head pain 6) back pain
	2) chest pain 7) joint pain
	3) stomach pain 8) tooth/ear pain
	4) neck pain 9) other
	5) muscle pain 10) other
14.	I have had persistent pain for months
	and years.
15.	If you know the cause of your persistent pain, please
	explain

- 16. Have you ever been treated at a pain clinic? Yes No
- 17. Are you currently being treated at a pain clinic? Yes No
- 18. Please circle the number of previous surgeries you have had because of your persistent pain?
  - 0 1 2 3 4 5 6 7 8 9 10 11+
- 19. Do you currently take mediation for your pain?

  Yes No

Please indicate how much you agree with each of the following
statements about your pain by using the following scale:
<pre>0 = This is very untrue for me.</pre>
1 = This is somewhat untrue for me.
2 = This is neither true nor untrue for me (or it does not
apply to me).
3 = This is somewhat true for me.
4 = This is very true for me.
1. There are many times when I can influence the amount of pain I feel.
0 1 2 3 4
2. The pain I usually experience is a signal that damage is being done.
0 1 2 3 4
3.I do not consider my pain to be a disability.
0 1 2 3 4
4.Nothing but my pain really bothers me.
0 1 2 3 4
5.Pain is a signal that I have not been exercising enough.
0 1 2 3 4
6.My family does not understand how much pain I am in.
0 1 2 3 4
7.I count more on my doctors to decrease my pain than I do on myself.
0 1 2 3 4
8.I will probably always have to take pain medications.
0 1 2 3 4

<pre>0 = This is very untrue for me.</pre>
1 = This is somewhat untrue for me.
2 = This is neither true nor untrue for me (or it does not
apply to me).
<pre>3 = This is somewhat true for me.</pre>
4 = This is very true for me.
9.When I hurt, I want my family to treat me better.
0 1 2 3 4
10.If my pain continues at its present level, I will be unable to work.
0 1 2 3 4
11. The amount of pain I feel is completely out of my control.
0 1 2 3 4
12.I do not expect a medical cure for my pain.
0 1 2 3 4
13. Pain does not necessarily mean that my body is being harmed.
0 1 2 3 4
14.I have had the most relief from pain with the use of medications.
0 1 2 3 4
15.Anxiety increases the pain I feel.
0 1 2 3 4
16. There is little that I or anyone can do to ease the pain I feel.
0 1 2 3 4
17. When I am hurting, people should treat me with care and concern.
0 1 2 3 4

<pre>0 = This is very untrue for me.</pre>
1 = This is somewhat untrue for me.
2 = This is neither true nor untrue for me (or it does not
apply to me).
3 = This is somewhat true for me.
4 = This is very true for me.
18.I pay doctors so they will cure me of my pain.
0 1 2 3 4
19.My pain problem does not need to interfere with my activity level.
0 1 2 3 4
20.My pain is not emotional, it is purely physical.
0 1 2 3 4
21.I have given up my search for the complete elimination of my pain
through the work of the medical profession.
0 1 2 3 4
22.It is the responsibility of my loved ones to help me when I feel
pain.
0 1 2 3 4
23. Stress in my life increases my pain.
0 1 2 3 4
24.Exercise and movement are good for my pain problem.
0 1 2 3 4
25. Just by concentrating or relaxing, I can "take the edge" off my pain.
0 1 2 3 4

0 =	This is	very	untrue	e for n	me.
1 =	This is	some	what ur	itrue i	for me.
2 =	This is	neith	ner tru	ue nor	r untrue for me (or it does not
	apply t	o me).			
3 =	This is	some	what to	ue for	or me.
4 =	This is	very	true i	or me	e.
26.1	will ge	et a jo	ob to e	earn mo	money regardless of how much pain I feel.
	0	1	2	3	4
27.Me	edicine	is one	e of the	ne best	st treatments for chronic pain.
	0	1	2	3	4
28.I	am unab	ole to	contro	ol a s	significant amount of my pain.
	0	1	2	3	4
29.A	doctor'	s job	is to	find e	effective pain treatments.
	0	1	2	3	4
30.M	y family	need:	s to le	earn ho	how to take better care of me when I am
	in pai	in.			
	0	1	2	3	4
31.De	epressio	on inc	reases	the pa	pain I feel.
	0	1	2	3	4
32.1	f I exer	cise,	I cou	ld make	ke my pain problem much worse.
	0	1	2	3	4
33.1	believe	e that	I can	contr	rol how much pain I feel by changing my
	though	nts.			
	0	1	2	3	4

0 =	This	is ve	ery untr	ue fo	or me.
1 =	This	is so	omewhat	untru	ue for me.
2 =	This	is ne	either t	rue n	nor untrue for me (or it does not
	apply	y to n	me).		
3 =	This	is so	omewhat	true	for me.
4 =	This	is ve	ery true	for	me.
34.0	ften 1	need	d more t	ender	loving care than I am now getting when
	I an	n in p	pain.		
	0	1	2	3	4
35.1	consi	ider m	myself t	o be	disabled.
•	0	1	2	3	4
36.1	wish	my do	octor wo	uld s	stop prescribing pain medications for me.
	0	1	2	3	4
37.M	y pain	is m	nostly e	motio	onal, and not so much a physical problem.
	0	1	2	3	4
38.S	omethi	ng is	wrong	with	my body which prevents much movement or
	exer	cise.			
	0	1	2	3	4
39.1	have	learn	ed to c	ontro	l my pain.
	0	1	2	3	4
10.1	trust	that	the me	dical	profession can cure my pain.
	0	1	2	3	4
11.I	know	for s	ure I ca	an lea	arn to manage my pain.
	0	1	2	3	4

0 =	This i	s very	untru	e for	me.
1 =	This i	s some	ewhat u	ıntrue	for me.
2 =	This i	s neit	her tr	ue nor	untrue for me (or it does not
	apply	to me)	•		
3 =	This i	s some	what t	rue fo	or me.
4 =	This i	s very	true	for me	•
42.M	y pain	does n	ot sto	p me f	rom leading a physically active life.
	0	1	2	3	4
43.My	physi	cal pa	in wil	l neve	r be cured.
	0	1	2	3	4
44.Th	ere is	a str	ong co	nnecti	on between my emotions and my pain level.
	0	1	2	3	4
45.1	can do	nearl	y ever	ything	as well as I could before I had a pain
	proble	em.			
	0	1	2	3	4
46.If	I do 1	not ex	ercise	regul	arly, my pain problem will continue to
	get w	orse.			
	0	1	2	3	4
17.I	am not	in co	ntrol (	of my p	pain.
	0	1	2	3	4
18.No	matter	how :	I feel	emotio	onally, my pain stays the same.
	0	1	2	3 .	4
9.Pa	in will	l neve	stop	me fro	om doing what I really want to do.
	0	1	2	3	4

<pre>0 = This is very untrue for me.</pre>
1 = This is somewhat untrue for me.
2 = This is neither true nor untrue for me (or it does not
apply to me).
3 = This is somewhat true for me.
4 = This is very true for me.
50.When I find the right doctor, he or she will know how to reduce
my pain.
0 1 2 3 4
51.If my doctor prescribed pain medications for me, I would throw
them away.
0 1 2 3 4
52. Whether or not a person is disabled by pain depends more on your
attitude than the pain itself.
0 1 2 3 4
53.I have noticed that if I can change my emotions, I can influence
my pain.
0 1 2 3 4
·

[\*[\*[PLEASE GO ON TO NEXT PAGE]\*]\*]

In the following 20 questions, you will be asked to describe your
pain and how it affects your life. Under each question is a scale
to record your answer. Read each question carefully and then CIRCLE
a number on the scale under that question to indicate how that specific
question applies to you.

									011101

Individuals who experience pain have developed a number of ways to cope, or deal, with their pain. These include saying things to themselves when they experience pain, or engaging in different activities. Below are a list of things that individuals have reported doing when they feel pain. For each activity, I want you to indicate, using the chart below, how much you engage in that activity when you feel pain, where a 0 indicates you never do that when you are experiencing pain, a 3 indicates you sometimes do that when you are experiencing pain, and a 6 indicates that you always do it when are experiencing pain. Remember, you can use any number along the scale.

0	1	2	3	4	5	6
Never			Sometimes			Always
do that			do that			do that

When I feel pain ...

- 1. I try to feel distant from the pain, almost as if the pain was in somebody else's body.
- 2. I leave the house and do something, such as going to the movies or shopping.
- \_\_\_\_ 3. I try to think of something pleasant.
- 4. I don't think of it as pain but rather as a dull or warm feeling.

The next set of questions are groups of statements. Please read each group of statements carefully. Then pick out one statement in each group which best describes the way you have been feeling the past week, including today. Circle the number beside the statement you picked. If several statements in the group seem to apply equally well, CIRCLE EACH ONE. Be sure to read all the statements in each group before making your choice.

- 1. 0 I do not feel sad
  - 1 I feel sad
  - 2 I am sad all the time and I can't snap out of it
  - I am so sad or unhappy that I can't stand it

- 2. 0 I am not particularly discouraged about the future
  - 1 I feel discouraged about the future
  - 2 I feel I have nothing to look forward to
  - 3 I feel that the future is hopeless and that things cannot improve
- 3. 0 I do not feel like a failure
  - 1 I feel that I have failed more than the average person
  - 2 As I look back on my life, all I can see is a lot of failures
  - 3 I feel I am a complete failure as a person
- 4. 0 I get as much satisfaction out of things as I used to
  - 1 I don't enjoy things the way I used to
  - 2 I don't get real satisfaction out of anything anymore
  - 3 I am dissatisfied or bored with everything
- 5. 0 I don't feel particularly quilty
  - 1 I feel guilty a good part of the time
  - 2 I feel guilty most of the time
  - 3 I feel guilty all of the time
- 6. 0 I don't feel I am being punished
  - 1 I feel I may be punished
  - 2 I expect to be punished
  - 3 I feel I am being punished
- 7. 0 I don't feel disappointed in myself.
  - 1 I am disappointed in myself
  - 2 I am disgusted with myself
  - 3 I hate myself

- 8. 0 I don't think I am any worse than anybody else
  - 1 I am critical of myself for my weaknesses or mistakes
  - 2 I blame myself all the time for my faults
  - 3 I blame myself for everything bad that happens
- 9. 0 I don't have any thoughts of killing myself
  - I have thoughts of killing myself, but I would never carry them out
  - 2 I would like to kill myself
  - 3 I would kill myself if I had the chance
- 10. 0 I don't cry anymore than usual
  - 1 I cry more than I used to
  - 2 I cry all the time now
  - I used to be able to cry, but now I can't cry even though I want to
- 11. 0 I am no more irritated than I ever am
  - 1 I get annoyed or irritated more easily than I used to
  - 2 I feel irritated all the time now
  - 3 I don't get irritated at all by the things that used to irritate me
- 12. 0 I have not lost interest in other people
  - 1 I am less interested in other people than I used to be
  - 2 I have lost most of my interest in other people
  - 3 I have lost all my interest in other people

- 13. 0 I make decisions about as well as I ever could
  - 1 I put off making decisions more than I used to
  - I have greater difficulty in making decisions than before
  - 3 I can't make decisions at all anymore
- 14. 0 I don't feel I look any worse than I used to
  - 1 I am worried that I am looking old and unattractive
  - I feel that there are permanent changes in my appearance that make me look unattractive
  - 3 I believe that I look ugly
- 15. 0 I can work about as well as before
  - 1 It takes an extra effort to get started at doing something
  - I have to push myself very hard to do anything
  - 3 I can't do any work at all
- 16. 0 I can sleep as well as usual
  - 1 I don't sleep as well as I used to
  - I wake up 1-2 hours earlier than I used to and find it hard to get back to sleep
  - 3 I wake up several hours earlier than I used to and cannot get back to sleep
- 17. 0 I don't get more tired than usual
  - 1 I get tired more easily than I used to
  - 2 I get tired from doing almost anything
  - 3 I am too tired to do anything

- 18. 0 My appetite is no worse than usual
  - 1 My appetite is not as good as it used to be
  - 2 My appetite is much worse now
  - 3 I have no appetite at all anymore
- 19. 0 I haven't lost much weight, if any lately
  - 1 I have lost more than 5 pounds I am purposely
  - 2 I have lost more than 10 pounds trying to lose
  - 3 I have lost more than 15 pounds weight. YES NO
- 20. 0 I am no more worried about my health than usual
  - I am worried about my problems such as aches and pains: or upset stomach; or constipation
  - I am very worried about physical problems and it's hard to think of much else
  - 3 I am so worried about my physical problems, that I cannot think about anything else
- 21. 0 I have not noticed any recent change in my interest in sex
  - 1 I am less interested in sex than I used to be
  - 2 I am much less interested in sex now
  - 3 I have lost interest in sex completely

1. Check the blank on the scale line below which best describes the degree of happiness, everything considered, of your present marriage. The middle point, "happy", represents the degree of happiness which most people get from marriage, and the scale gradually ranges on one side to those few who are very unhappy in marriage, and on the other, to those few who experience extreme joy or felicity in marriage.

#### IMPORTANT:

# DO NOT READ UNTIL YOU HAVE COMPLETED THE QUESTIONNAIRE DEBRIEFING SHEET

People who have persistent pain appear to report wide variability in their physical and psychological adjustment. Some people who have persistent pain seem to function and lead normal lives. These people seem to have adequate social supports, behavioral regimes, cognitive appraisals, and/or emotional stability to deal effectively with their pain. Others seem completely overwhelmed by their pain resulting in their pain becoming the primary focus of their lives. These people usually believe their pain will be permanently disabling and they may use maladaptive coping strategies to deal with their pain. Researchers are attempting to identify important variables that relate to these different outcomes that pain subjects report.

Pain has been conceptualized as more than a physical problem but rather as a complex multidimensional phenomenon with bio-physiological, psychological, and social components. Hence, it is becoming standard for pain patients who seek treatment to undergo a comprehensive assessment that evaluates not only the patient's medical findings, but also, the patient's coping strategies, and physical and psychological adjustment to the pain (William & Keefe, 1991). In addition, the social context in which the pain patient dwells is viewed as an important variable of interest. For instance, Burman and Margolin (1992) conducted an extensive review evaluating the relationship between marital relationships and health problems. From this review, they concluded that sufficient evidence is available to strongly support the hypothesis that the patient's social context is a significant contributor to the patient's health or illness. Also, pain-specific beliefs have been recognized as adding an important contribution to the pain experience. These beliefs have been shown to be associated with the pain patient's choice of coping strategies and level of adjustment (Jensen & Koroly, 1991).

The purpose of this study is to investigate the relationships between the "pain-free" (i.e., without persistent pain for a minimum of one year) spouse's pain-specific beliefs and behaviour and the pain subject's pain-specific beliefs, coping strategies, and adjustment. Marital satisfaction will be hypothesized as contributing a significant amount to some of these relationships.

### PERSISTENT PAIN AND FAMILIES RESEARCH QUESTIONNAIRE

TO BE FILLED OUT BY THE PARENT WHO DOES NOT HAVE PERSISTENT PAIN

Persistent pain can be a depressing and limiting condition. Research is

beginning to show that families may plays a role in how people adjust

with their pain. Researchers in the Psychology Department at the

University of Manitoba are trying to better understand which family

variables are related to pain adjustment.

I \_\_\_\_\_\_ hereby agree to take part in this project on the understanding that the information I provide will be kept strictly confidential and that I can withdraw from this project at any time.

## PAIN RESEARCH QUESTIONNAIRE

Code 1	10	
1. DATE OF BIRTH: DAY MONTH YEAR		
2. Gender: a) Male b) Female

The next set of questions are groups of statements. Please read each group of statements carefully. Then pick out one statement in each group which best describes the way you have been feeling the past week, including today. Circle the number beside the statement you picked. If several statements in the group seem to apply equally well, CIRCLE EACH ONE. Be sure to read all the statements in each group before making your choice.

- 1. 0 I do not feel sad
  - 1 I feel sad
  - I am sad all the time and I can't snap out of it
  - 3 I am so sad or unhappy that I can't stand it
     [\*[\*[PLEASE GO ON TO NEXT PAGE]\*]\*]

- 2. 0 I am not particularly discouraged about the future
  - 1 I feel discouraged about the future
  - 2 I feel I have nothing to look forward to
  - 3 I feel that the future is hopeless and that things cannot improve
- 3. 0 I do not feel like a failure
  - 1 I feel that I have failed more than the average person
  - 2 As I look back on my life, all I can see is a lot of failures
  - 3 I feel I am a complete failure as a person
- 4. 0 I get as much satisfaction out of things as I used to
  - 1 I don't enjoy things the way I used to
  - 2 I don't get real satisfaction out of anything anymore
  - 3 I am dissatisfied or bored with everything
- 5. 0 I don't feel particularly guilty
  - 1 I feel guilty a good part of the time
  - 2 I feel guilty most of the time
  - 3 I feel guilty all of the time
- 6. 0 I don't feel I am being punished
  - 1 I feel I may be punished
  - 2 I expect to be punished
  - 3 I feel I am being punished
- 7. 0 I don't feel disappointed in myself
  - 1 I am disappointed in myself
  - 2 I am disgusted with myself
  - 3 I hate myself

- 8. 0 I don't think I am any worse than anybody else
  - 1 I am critical of myself for my weaknesses or mistakes
  - 2 I blame myself all the time for my faults
  - 3 I blame myself for everything bad that happens
- 9. 0 I don't have any thoughts of killing myself
  - I have thoughts of killing myself, but I would never carry them out
  - 2 I would like to kill myself
  - 3 I would kill myself if I had the chance
- 10. 0 I don't cry anymore than usual
  - 1 I cry more than I used to
  - 2 I cry all the time now
  - I used to be able to cry, but now I can't cry even though I want to
- 11. 0 I am no more irritated than I ever am
  - 1 I get annoyed or irritated more easily than I used to
  - 2 I feel irritated all the time now
  - 3 I don't get irritated at all by the things that used to irritate me
- 12. 0 I have not lost interest in other people
  - 1 I am less interested in other people than I used to be
  - 2 I have lost most of my interest in other people
  - . 3 I have lost all my interest in other people

- 13. 0 I make decisions about as well as I ever could
  - 1 I put off making decisions more than I used to
  - I have greater difficulty in making decisions than before
  - 3 I can't make decisions at all anymore
- 14. 0 I don't feel I look any worse than I used to
  - 1 I am worried that I am looking old and unattractive
  - I feel that there are permanent changes in my appearance that make me look unattractive
  - 3 I believe that I look ugly
- 15. 0 I can work about as well as before
  - 1 It takes an extra effort to get started at doing something
  - 2 I have to push myself very hard to do anything
  - 3 I can't do any work at all
- 16. 0 I can sleep as well as usual
  - 1 I don't sleep as well as I used to
  - I wake up 1-2 hours earlier than I used to and find it hard to get back to sleep
  - 3 I wake up several hours earlier than I used to and cannot get back to sleep
- 17. 0 I don't get more tired than usual
  - 1 I get tired more easily than I used to
  - 2 I get tired from doing almost anything
  - 3 I am too tired to do anything

- 18. 0 My appetite is no worse than usual
  - 1 My appetite is not as good as it used to be
  - 2 My appetite is much worse now
  - 3 I have no appetite at all anymore
- 19. 0 I haven't lost much weight, if any lately
  - 1 I have lost more than 5 pounds I am purposely
  - 2 I have lost more than 10 pounds trying to lose
  - 3 I have lost more than 15 pounds weight. YES\_\_\_NO\_\_\_
- 20. 0 I am no more worried about my health than usual
  - I am worried about my problems such as aches and pains: or upset stomach; or constipation
  - I am very worried about physical problems and it's hard to think of much else
  - I am so worried about my physical problems, that I cannot think about anything else
- 21. 0 I have not noticed any recent change in my interest in sex
  - 1 I am less interested in sex than I used to be
  - 2 I am much less interested in sex now
  - 3 I have lost interest in sex completely

1. Check the blank on the scale line below which best describes the
degree of happiness, everything considered, of your present marriage.
The middle point, "happy", represents the degree of happiness which
most people get from marriage, and the scale gradually ranges on one
side to those few who are very unhappy in marriage, and on the other,
to those few who experience exteme joy or felicity in marriage.

#### IMPORTANT:

DO NOT READ UNTIL YOU HAVE COMPLETED THE QUESTIONNAIRE DEBRIEFING SHEET

People who have persistent pain appear to report wide variability in their physical and psychological adjustment. Some people who have persistent pain seem to function and lead normal lives. These people seem to have adequate social supports, behavioral regimes, cognitive appraisals, and/or emotional stability to deal effectively with their pain. Others seem completely overwhelmed by their pain resulting in their pain becoming the primary focus of their lives. These people usually believe their pain will be permanently disabling and they may use maladaptive coping strategies to deal with their pain. Researchers are attempting to identify important variables that relate to these different outcomes that pain subjects report.

Pain has been conceptualized as more than a physical problem but rather as a complex multidimensional phenomenon with bio-physiological, psychological, and social components. Hence, it is becoming standard for pain patients who seek treatment to undergo a comprehensive assessment that evaluates not only the patient's medical findings, but also, the patient's coping strategies, and physical and psychological adjustment to the pain (William & Keefe, 1991). In addition, the social context in which the pain patient dwells is viewed as an important variable of interest. For instance, Burman and Margolin (1992) conducted an extensive review evaluating the relationship between marital relationships and health problems. From this review, they concluded that sufficient evidence is available to strongly support the hypothesis that the patient's social context is a significant contributor to the patient's health or illness. Also, pain-specific beliefs have been recognized as adding an important contribution to the pain experience. These beliefs have been shown to be associated with the pain patient's choice of coping strategies and level of adjustment (Jensen & Koroly, 1991).

The purpose of this study is to investigate the relationships between the "pain-free" (i.e., without persistent pain for a minimum of one year) spouse's pain-specific beliefs and behaviour and the pain subject's pain-specific beliefs, coping strategies, and adjustment. Marital satisfaction will be hypothesized as contributing a significant amount to some of these relationships.

APPENDIX C

## STUDENTS MUST TAKE ONE OF THESE FORMS HOME FOR THEIR

#### PARENTS TO SIGN AND

## MUST BRING FORM SIGNED ON DAY OF SESSION

#### REQUEST FOR PARTICIPATION FORM

Persistent pain can be a depressing and limiting condition. Research is beginning to show that how people think about and cope with their pain plays a role in how people adjust with their pain. Also, the family is considered a key factor in the persistent pain person's life. Researchers in the Psychology Department at the University of Manitoba are trying to better understand which factors are related to adjustment. Your son/daughter has requested to participate in a study on families. Therefore, your help is also requested. Your son/daughter will bring home a questionnare for each parent to complete independently. This questionnaire will take approximately 45 to 60 minutes to complete. Upon returning your questionnaires, your son/daughter will receive credits towards his or her introductory psychology course. IF ONE PARENT HAS PERSISTENT PAIN (PAIN ONE OR MORE TIMES A WEEK AT THE SAME LOCATION FOR THREE MONTHS OR LONGER) THEN YOU BOTH ARE ELIGIBLE TO PARTICIPATE IN THIS RESEARCH PROJECT.

### Parent who has persistent pain

(1) I \_\_\_\_\_\_ hereby agree to take part in this project on the understanding that the information I provide will be kept strictly confidential and that I can withdraw from this project at any time.

## Spouse of the individual who has persistent pain

hereby agree to take part in this project on the understanding that the information I provide will be kept strictly confidential and that I can withdraw from this project at any time.

NOTE: IF THIS PARENT WHO SIGNED AT THE SECOND BLANK HAS PAIN ONE OR MORE TIMES A WEEK AT THE SAME LOCATION FOR THREE MONTHS OR LONGER THEN YOU BOTH BECOME INELIGIBLE FOR THIS STUDY. YOUR SON/DAUGHTER WILL STILL BE ABLE TO EARN ONE INTRODUCTORY PSYCHOLOGY CREDIT.

In the following 20 questions, you will be asked to describe your
parent's pain and how it affects your life. Under each question is a
scale to record your answer. Read each question carefully and then
CIRCLE a number on the scale under that question to indicate how that
specific question applies to you.

sca	le to	record	your a	nswer.	Read ea	ch ques	tion o	carefully and then	
CIR	CLE a	number	on the	scale	under t	hat que	stion	to indicate how that	
spe	cific	questi	on appl	ies to	you.				
1.	Rate	what Y	OU THIN	K the l	evel of	your p	arent'	's pain at the present	-
	mome	nt is.							
		0	1	2	3	4	5	6	
	No	pain					7	Jery intense pain	
2.	In g	eneral,	how mu	ch does	your pa	arent's	pain	problem interfere wit	h
	your	day to	day ac	tivitie	s?				
		0	1	2	3	4	5	6	
	No i	nterfer	ence				E	Extreme interference	
3.	Since	e the t	ime you	r paren	t's deve	eloped a	a pain	n problem, how much	
	has y	your pa	rent's p	pain cha	anged yo	our amou	unt to	work?	
		0	1	2	3	4	5	6	
	No ch	nange					Ex	treme change

The next set of questions are groups of statements. Please read each group of statements carefully. Then pick out one statement in each group which best describes the way you have been feeling the past week, including today. Circle the number beside the statement you picked. If several statements in the group seem to apply equally well, CIRCLE EACH ONE. Be sure to read all the statements in each group before making your choice.

- 1. 0 I do not feel sad
  - 1 I feel sad
  - I am sad all the time and I can't snap out of it
  - 3 I am so sad or unhappy that I can't stand it
     [\*[\*[PLEASE GO ON TO NEXT PAGE]\*]\*]

- 2. 0 I am not particularly discouraged about the future
  - 1 I feel discouraged about the future
  - 2 I feel I have nothing to look forward to
  - 3 I feel that the future is hopeless and that things cannot improve
- 3. 0 I do not feel like a failure
  - 1 I feel that I have failed more than the average person
  - 2 As I look back on my life, all I can see is a lot of failures
  - 3 I feel I am a complete failure as a person
- 4. 0 I get as much satisfaction out of things as I used to
  - 1 I don't enjoy things the way I used to
  - 2 I don't get real satisfaction out of anything anymore
  - 3 I am dissatisfied or bored with everything
- 5. 0 I don't feel particularly guilty
  - 1 I feel guilty a good part of the time
  - 2 I feel guilty most of the time
  - 3 I feel guilty all of the time
- 6. 0 I don't feel I am being punished
  - 1 I feel I may be punished
  - 2 I expect to be punished
  - 3 I feel I am being punished
- 7. 0 I don't feel disappointed in myself
  - 1 I am disappointed in myself
  - 2 I am disgusted with myself
  - 3 I hate myself

- 8. 0 I don't think I am any worse than anybody else
  - 1 I am critical of myself for my weaknesses or mistakes
  - 2 I blame myself all the time for my faults
  - 3 I blame myself for everything bad that happens
- 9. 0 I don't have any thoughts of killing myself
  - 1 I have thoughts of killing myself, but I would never carry them out
  - 2 I would like to kill myself
  - 3 I would kill myself if I had the chance
- 10. 0 I don't cry anymore than usual
  - 1 I cry more than I used to
  - 2 I cry all the time now
  - 3 I used to be able to cry, but now I can't cry even though I want to
- 11. 0 I am no more irritated than I ever am
  - 1 I get annoyed or irritated more easily than I used to
  - 2 I feel irritated all the time now
  - 3 I don't get irritated at all by the things that used to irritate me
- 12. 0 I have not lost interest in other people
  - 1 I am less interested in other people than I used to be
  - 2 I have lost most of my interest in other people
  - 3 I have lost all my interest in other people

- 13. 0 I make decisions about as well as I ever could
  - 1 I put off making decisions more than I used to
  - I have greater difficulty in making decisions than before
  - 3 I can't make decisions at all anymore
- 14. 0 I don't feel I look any worse than I used to
  - 1 I am worried that I am looking old and unattractive
  - I feel that there are permanent changes in my appearance that make me look unattractive
  - 3 I believe that I look ugly
- 15. 0 I can work about as well as before
  - 1 It takes an extra effort to get started at doing something
  - I have to push myself very hard to do anything
  - 3 I can't do any work at all
- 16. 0 I can sleep as well as usual
  - 1 I don't sleep as well as I used to
  - I wake up 1-2 hours earlier than I used to and find it hard to get back to sleep
  - 3 I wake up several hours earlier than I used to and cannot get back to sleep
- 17. 0 I don't get more tired than usual
  - 1 I get tired more easily than I used to
  - 2 I get tired from doing almost anything
  - 3 I am too tired to do anything

- 18. 0 My appetite is no worse than usual
  - 1 My appetite is not as good as it used to be
  - 2 My appetite is much worse now
  - 3 I have no appetite at all anymore
- 19. 0 I haven't lost much weight, if any lately
  - 1 I have lost more than 5 pounds I am purposely
  - 2 I have lost more than 10 pounds trying to lose
  - 3 I have lost more than 15 pounds weight. YES NO
- 20. 0 I am no more worried about my health than usual
  - I am worried about my problems such as aches and pains: or upset stomach; or constipation
  - I am very worried about physical problems and it's hard to think of much else
  - 3 I am so worried about my physical problems, that I cannot think about anything else
- 21. 0 I have not noticed any recent change in my interest in sex
  - 1 I am less interested in sex than I used to be
  - 2 I am much less interested in sex now
  - 3 I have lost interest in sex completely

The statements listed below describe situations which could happen in a family. For each statement below, please circle "T" if the statement describes your family most of the time, or "F" if the statement does not describe your family most of the time.

- T F 1. Family members really help and support one another.
- T F 2. Family members often keep their feelings to themselves.
- T F 3. We fight a lot in our family.
- T F 4. We don't do things on our own very often in our family.
- T F 5. We feel it is important to be good at whatever you do.
- T F 6. We often talk about political and social problems.
- T F 7. We spend most weekends and evenings at home.
- F 8. Family members attend church, synagogue, or Sunday school fairly often.
- T F 9. Activities in our family are pretty carefully planned.
- T F 10. Family members are rarely ordered around.
- T F 11. We often seem to be killing time at home.
- T F 12. We say anything we want to around home.
- T F 13. Family members rarely become openly angry.
- T F 14. In our family, we are strongly encouraged to be independent.
- T F 15. Getting ahead in life is very important in our family.
- T F 16. We rarely go to lectures, plays, or concerts.
- T F 17. Fiends often come over for dinner or to visit.
- T F 18. We don't say prayers in our family.
- T F 19. We are generally very neat and orderly.
- T F 20. There are very few rules to follow in our family.
- T F 21. We put a lot of energy into what we do at home.
- T F 22. It's hard to "blow off steam" at home without upsetting somebody.
- T F 23. Family members sometimes get so angry they throw things.
- T F 24. We think things out for ourselves in our family.
- T F 25. How much money a person makes is not very important to us.
- T F 26. Learning about new and different things is very important in our family.
- T F 27. Nobody in our family is active in sports, Little League, bowling, etc.
- T F 28. We often talk about the religious meanings of Christmas, Passover, or other holidays.
- T F 29. It's often hard to find things when you need them in our household.
- T F 30. There is one family member who makes most of the decisions.
- T F 31. There is a feeling of togetherness in our family.
- T F 32. We tell each other about our personal problems.
- T F 33. Family members hardly ever lose their tempers.
- T F 34. We come and go as we want to in our family.
- T F 35. We believe in competition and "may the best man win".
- T F 36. We are not interested in cultural activities.
- T F 37. We often go to movies, sports events, camping, etc.
- T F 38. We don't believe in heaven or hell.
- T F 39. Being on time is very important in our family.

- T F 40. There are set ways of doing things at home.
- T F 41. We rarely volunteer when something has to be done at home.
- T F 42. If we feel like doing something on the spur of the moment we often just pick up and go.
- T F 43. Family members often critize each other.
- T F 44. There is very little privacy in our family.
- T F 45. We always strive to do things just a little better the next time.
- T F 46. We rarely have intellectual discussions.
- T F 47. Everyone in our family has a hobby or two.
- T F 48. Family members have strict ideas about what is right and wrong.
- T F 49. People change their minds often in our family.
- T F 50. There is a strong emphasis on following rules in our family.
- T F 51. Family members really back each other up.
- T F 52. Someone usually gets upset if you complain in our family.
- T F 53. Family members sometimes hit each other.
- T F 54. Family members almost always rely on themselves when a problem comes up.
- T F 55. Family members rarely worry about job promotions.
- T F 56. Someone in our family plays a musical instrument.
- T F 57. Family members are not very involved in recreational activities outside work or school.
- T F 58. We believe there are some things you have to take on faith.
- T F 59. Family members make sure their rooms are neat.
- T F 60. Everyone has an equal say in family decisions.
- T F 61. There is very little group spirit in our family.
- T F 62. Money and paying bills is openly talked about in our family.
- T F 63. If there's a disagreement in our family, we try hard to smooth things over and keep the peace.
- T F 64. Family members strongly encourage each other to stand up for their rights.
- T F 65. In our family, we don't try hard to succeed.
- F 66. Family members often go to the library.
- T F 67. Family members sometimes attend courses or take lessons for some hobby of interest (outside of school).
- T F 68. In our family, each person has different ideas about what is right and wrong.
- T F 69. Each person's duties are clearly defined in our family.
- T F 70. We can do whatever we want to in our family.
- T F 71. We really get along well with each other.
- T F 72. We are usually careful about what we say to each other.
- T F 73. Family members often try to one-up or outdo each other.
- T F 74. It's hard to be by yourself without hurting someone's feelings in our household.
- T F 75. "Work before play" is the rule in our family.
- T F 76. Watching TV is more important than reading in our family.
- T F 77. Family members go out a lot.
- T F 78. The Bible is a very important book in our home.
- F 79. Money is not handled very carefully in our family.
- F 80. Rules are pretty inflexible in our household.

- T F 81. There is plenty of time and attention for everyone in our family.
- T F 82. There are a lot of spontaneous discussions in our family.
- T F 83. In our family, we believe you don't ever get anywhere by raising your voice.
- T F 84. We are not really encouraged to speak up for ourselves in our family.
- T F 85. Family members are often compared with others as to how well they are doing at work or school.
- T F 86. Family members really like music, art, and literature.
- T F 87. Our main form of entertainment is watching TV or listening to the radio.
- F F 88. Family members believe that if you sin you will be punished.
- T F 89. Dishes are usually done immediately after eating.
- T F 90. You can't get away with much in our family.

### IMPORTANT:

DO NOT READ UNTIL YOU HAVE COMPLETED THE QUESTIONNAIRE DEBRIEFING SHEET

People who have persistent pain appear to report wide variability in their physical and psychological adjustment. Some people who have persistent pain seem to function and lead normal lives. These people seem to have adequate social supports, behavioral regimes, cognitive appraisals, and/or emotional stability to deal effectively with their pain. Others seem completely overwhelmed by their pain resulting in their pain becoming the primary focus of their lives. These people usually believe their pain will be permanently disabling and they may use maladaptive coping strategies to deal with their pain. Researchers are attempting to identify important variables that relate to these different outcomes that pain subjects report.

Pain has been conceptualized as more than a physical problem but rather as a complex multidimensional phenomenon with bio-physiological, psychological, and social components. Hence, it is becoming standard for pain patients who seek treatment to undergo a comprehensive assessment that evaluates not only the patient's medical findings, but also, the patient's coping strategies, and physical and psychological adjustment to the pain (William & Keefe, 1991). In addition, the social context in which the pain patient dwells is viewed as an important variable of interest. For instance, Burman and Margolin (1992) conducted an extensive review evaluating the relationship between marital relationships and health problems. From this review, they concluded that sufficient evidence is available to strongly support the hypothesis that the patient's social context is a significant contributor to the patient's health or illness. Also, pain-specific beliefs have been recognized as adding an important contribution to the pain experience. These beliefs have been shown to be associated with the pain patient's choice of coping strategies and level of adjustment (Jensen & Koroly, 1991).

The purpose of this study is to investigate the relationships between the "pain-free" (i.e., without persistent pain for a minimum of one year) spouse's pain-specific beliefs and behaviour and the pain subject's pain-specific beliefs, coping strategies, and adjustment. Marital satisfaction will be hypothesized as contributing a significant amount to some of these relationships.

APPENDIX E

#### INFORMATION SHEET

Dear Parents,

Thank you for taking the time to read this information sheet. Research in the area of pain is just beginning to show that family members can play a significant role in the life of the individual who is experiencing persistent pain. By taking part in this study, you will help to contribute to further our understanding of which family variables are most important. Because we are interested in the family we strongly request that both parents complete questionnaires. It is also very important that you complete the entire questionnaire, not omitting any parts. Please do NOT do the questionnaires together or discuss the questionnaires before completing them. If you have any questions with regard to this research study, please feel free to contact the primary investigator daily between 8 and 9pm.

Thank you in advance for your participation in this research project.

Ian Mogilevsky, B.A.(Honors)

Primary Investigator

Michael R. Thomas, Ph.D., C.Psych.

Supervising Clinical Psychologist

P.S. In the <u>very rare</u> case that items on your questionnaire are unclear and there is need for clarification, we would like permission to phone you to obtain this information.

Please	give	permission	by	initia	aling	here
