ABSTRACT

This practicum puts forward the operational cost saving criterion as one method which may be used to help allocate economic resources between ten remote communities in Northern Manitoba, for the purpose of upgrading airstrip landing facilities.

All of the costs, both public and private, which are associated with the delivery air transport needs on a Ministry of Transport designated Class 2, regular specific point commercial air service, are calculated for a five year planning period. These costs, infra-structural, operations and maintenance and passenger and freight delivery via each of three types of aircraft, the de Havilland Twin Otter, the Douglas DC-3 and the de Havilland Dash 7, are discounted at an appropriate rate of discount for each year in which they occur in order to derive the cumulative net present value of each alternative. A given pattern of air transport demand along a route serving the ten communities is assumed. The cumulative net present values of the alternatives are then compared first for the delivery of all of the communities' freight requirement by each alternative aircraft and then similarly for the passenger requirement. Operational cost savings occur when the additional costs of airport infrastructure necessary to accomodate larger more cost efficient aircraft

are positively offset by the operating economies offered by larger capacity aircraft. Communities are then prioritized for the purpose of additional airstrip construction according to the percentage cost saving generated by one alternative over another. Communities where higher costs savings may be generated by the building of additional airstrip capacity are given order of preference for airport upgrading.

ACKNOWLEDGMENTS

In recognition of the assistance provided in the preparation of this practicum, I wish to thank the members of my committee, Dr. Gregory Mason (Chairman), Professor of Economics, the University of Manitoba; Mr. David O'Brien, Manager, Regulatory Affairs, Transair Ltd., Winnipeg and Mr. John Reader, Head, Engineering & Construction Services, The Manitoba Department of Northern Affairs, Thompson, Manitoba.

I wish to express my gratitude to Dr. Paul Nickel and Mr. Thomas Henley of the Natural Resource Institute, the University of Manitoba for suggestions and advice offered regarding this practicum during its preparation. I also wish to thank Mr. Frank Duval, Superintendant of Airport Operations & Maintenance, The Manitoba Department of Northern Affairs, for his generous offering of information and time. I am grateful to Mr. Terry Partridge of the Manitoba Government Planning Secretariat for helping to put this study into the proper perspective with respect to the development of a northern transportation policy for Manitoba.

This practicum was made possible by a fellowship granted by the Transportation Development Agency, Ministry of Transport, Montreal. I am deeply grateful for the opportunity to do research that was provided by the fellowship.

Finally, I owe a special thank you to Mrs. Marjorie McBride for taking the time and responsibility for typing this report.

CHAPTER I

Introduction

THE IMPORTANCE OF THE STUDY

The physical geography of much of Northern Manitoba makes the development of transportation infrastructure difficult and often extremely expensive. Large areas of muskeg and rock outcroppings create difficulties in the location and construction of airstrips at remote communities.

Under these circumstances, the high costs of upgrading airstrips at the communities in this proposed study, dictate that any new investments undertaken to increase airstrip capacity be evaluated thoroughly.

Airstrip upgrading decisions are of critical importance to the future of the concerned communities as they relate to the more economical delivery of necessary goods and improved passenger service. The resolution of upgrading issues is vital in the interests of safe, fast and economical air service to these communities. For these reasons it is believed this proposed study can make a valuable contribution to the public decision-making process in this area.

An Historical Review of Manitoba Government Policy

The Airport Development Program for remote northern communities in Manitoba was launched in 1966-67. The policy of the Commission of Northern Affairs was to proceed on requests to build airstrips at remote communities with a population of 100 people or more. The purpose of the policy was to provide year-round VFR air transportation access to those communities not connected to southern Manitoba or larger service centres by a surface mode of transportation on a permanent basis.

The program did not exclude Indian Reserves, but as funds were limited, work proceeded with assistance from Winter Works and Fisherman's Compensation programs and the Federal Department of Indian Affairs.

By 1970, thirty-one airstrips were under construction and some degree of operation and maintenance activity was in progress.

The original purpose of the Airport Development Program placed emphasis on the provision of very basic landing facilities which could provide access during the winter freeze-up and spring break-up periods and meet the needs of emergency medical situations. However, many of

the airstrips have outgrown their original functions. Usage has grown tremendously in the past few years and the need for more expensive, sophisticated and reliable facilities has increased. The two busiest remote airstrips in the province, Garden Hill and Norway House, recorded total aircraft movements of 10,784 and 10,108 respectively in the 1975-76 period.¹

For these airstrips, this represents an increase of 21 percent at Garden Hill and nearly 9 percent at Norway House over the previous one year period.

As the role of many remote airstrips has evolved to include the requirement of higher quality landing and support facilities, an increased strain has been placed on the economic resources of the province. While the further development of criteria to govern the initial investment in remote airstrips remains a concern, the need for economic criteria to aid in decisions relating to the upgrading or re-classification of already existing facilities has become increasingly apparent.

¹ Province of Manitoba, Department of Northern Affairs Local Services Division, Airport Activity Summary 1975-76.

Note: For additional information concerning the historical development of Manitoba Government Air Transportation Policy for remote communities, please see Appendix A, Air Transportation Policy and Strategy for Remote Communities in Manitoba, J.D. Collinson, 1971.

A REVIEW OF RECENT STUDIES

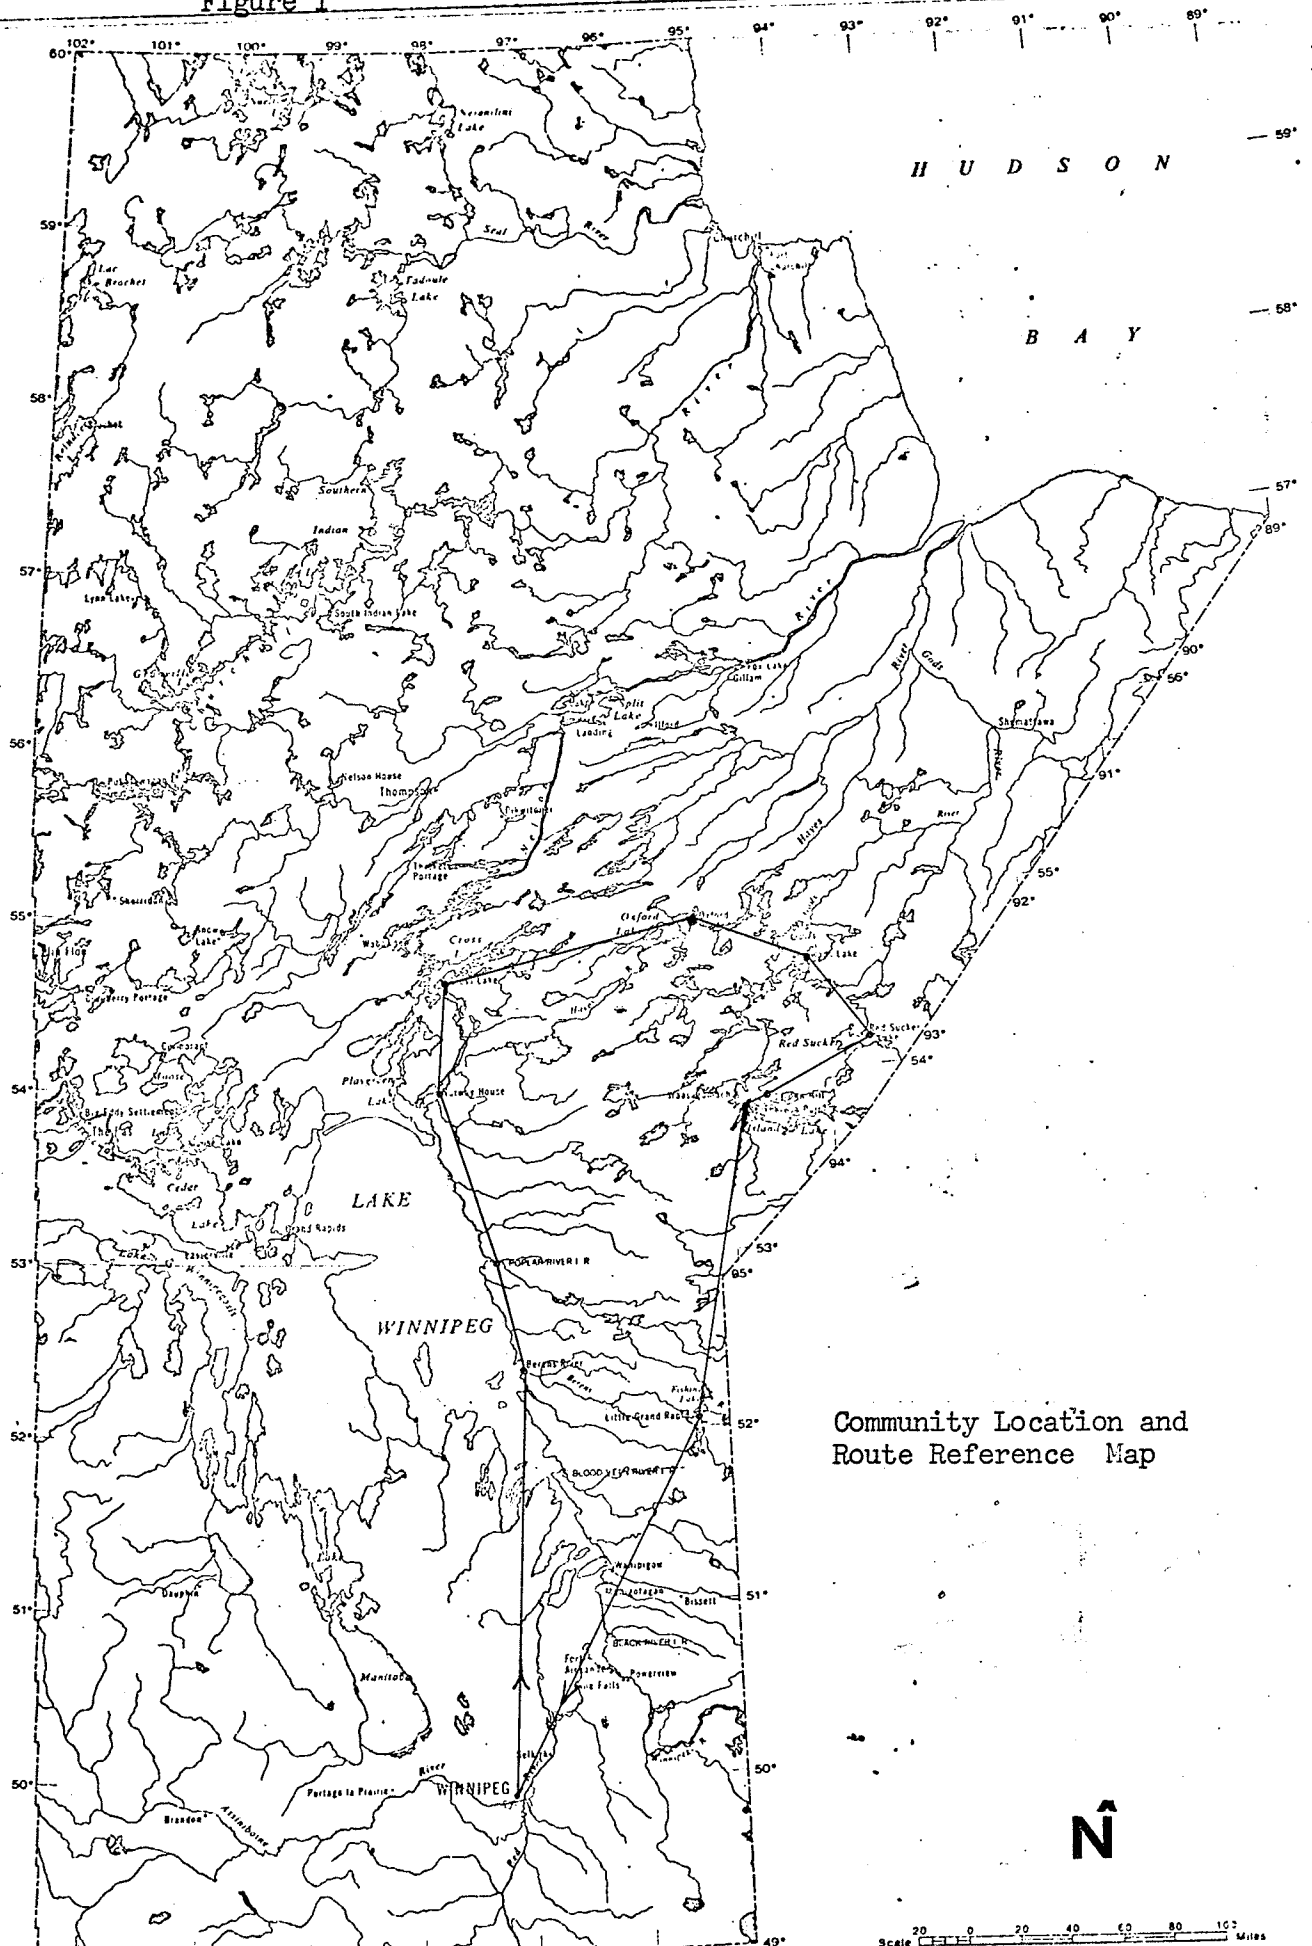

Studies done prior to, and including 1974, in the area of northern transportation to remote communities in Manitoba, were directed at synthesizing information from a wide variety of sources in order to gain a better understanding of the behaviour of transportation in Northern Manitoba.¹ These studies contributed to our knowledge of the subject by describing the level of demand for goods and services at remote communities and by examining the degree of modal split occurring in the delivery of passengers and goods between the various transportation alternatives.

The most recent comprehensive study of transportation in Northern Manitoba, evaluates the economic efficiency of a large number of possible transportation alternatives.² The measure of economic efficiency used is the operational cost saving criterion. The air transportation section of the study evaluates alternatives on

1. Materials for the Development of Remote Airstrips in Manitoba, K.A.J. Davidson, Winnipeg, Manitoba. The Department of Northern Affairs, 1974 and A Study of Freight Transportation to Remote Northern Communities, Mackenzie, Ruhr, Simpson Main Report, Winnipeg, Manitoba, 1973.
2. Manitoba Northlands Transportation Study, an Economic Evaluation of Transport System Alternatives, Hickling Johnston Ltd., Toronto, Ontario, 1975.

a point to point basis. This introduces some distortion into the way in which the air transport system actually operates. Like the Hickling Johnston report, this practicum expresses the economic benefits or disbenefits of alternatives in terms of operational cost savings. A major difference is that the alternatives evaluated are compared along a route and thus the costs of delivery of goods and passengers more closely represent actual costs. The other significant difference between the Hickling Johnston study and this practicum is that the analysis undertaken here considers additional investments made at each airstrip to be a separate project rather than part of a combined air transportation package.

Figure 1

CHAPTER II

THE PROBLEM AND ITS SETTING

The Statement of the Problem

The purpose of this practicum is to develop a practical model which may be used to evaluate decisions relating to the construction of additional capacity to airstrips at selected remote communities in Northern Manitoba.

The Subproblems

The first subproblem. The first subproblem will be to determine the total private and public cost of servicing the communities' current air transport needs, using the existing landing facilities and operating equipment.

The second subproblem. The second subproblem will be to derive an estimate of the growth in demand for goods and passenger movement, by air, to the communities considered.

The third subproblem. The third subproblem is to estimate the probable costs of additional airstrip capacity, at each community, that would be necessary in order to handle more cost efficient aircraft. Also, the probable direct operating costs of such aircraft will be determined.

The fourth subproblem. The fourth subproblem will be to compare the direct monetary benefits of servicing these communities' future air transport needs using the existing delivery system or by using upgraded ground facilities and more cost efficient aircraft.

The Hypothesis

There is at present no commonly accepted method that is applied to the issues involved in deciding whether or not to upgrade the landing facilities at remote airstrips in Northern Manitoba. On the basis of operational cost savings, the direct benefits and costs of additional airstrip investment at the selected communities can be evaluated. Upgrading decisions are critical to the economic future of these remote communities. To the extent that the results of the analysis can be interpreted, the effect of upgrading decisions will be discussed as they relate to lower delivery costs of goods and faster more frequent passenger service.

The Delimitations

There are certain social goals that the provision of air access to remote communities can help to fulfill. One important consideration is the need to provide remote settle-

ment with access to medical relief during times of emergency, especially during periods of spring break-up or winter freeze-up when many communities are cut off from surface modes of transportation. The criteria that may be used, in such circumstances to govern the initial investment in basic airstrip facilities will not be discussed.

Modes of transportation, other than air, may be discussed only in so far as they affect the immediate objectives of this study.

The role of the Ministry of Transport and the Canadian Transport Commission in the provision of air service to the communities in this study, is of a regulatory nature. Their authority in the areas of aircraft safety, airstrip construction standards, the licensing of carriers and the approval of routes, schedules and tariffs, will only be discussed in so far as they affect the main purpose of this study.

The role of air transportation as an instrument of economic and social development is beyond the scope of this study.

The analysis of the communities as a network with regular routes and schedules, precludes the inclusion of information about goods and passengers moved on a charter

basis.

This study does not address itself to the problem of 'rationalizing' northern air service.

The Definition of Terms

Practical model. The term 'practical model' in the context of this study refers to the attempt to view a group of selected communities as a subsystem of the northern air transportation network. The total costs of serving the communities by air will then be determined. These costs will be analyzed using the benefit - cost method. The benefits of additional investments to airstrips can then be evaluated in terms of any operational cost savings to be obtained by serving the transport needs of the communities by more cost efficient aircraft, compared to the continued use of present landing facilities and operating equipment.

Additional capacity cost. Additional capacity cost is the marginal investment necessary to make each airstrip capable of accomodating more cost efficient aircraft than are presently being utilized.

Remote community. Remote communities for the purposes of this study, are, those communities which are not served by

a surface mode of transportation on a permanent basis.

Selected communities. The communities that have been selected for this study are remote communities in Northeast and the East side of Lake Winnipeg, North of the Winnipeg River. They are currently served by Midwest Airlines Ltd. of Winnipeg on a regular scheduled basis from Winnipeg. They are:

Berens River	Gods Lake Narrows
* Poplar River	* Red Sucker Lake
Norway House	Garden Hill
Cross Lake	* Ste. Therese Point
* Oxford House	* Little Grand Rapids

Public costs. Public costs are those expenditures made by the Manitoba Department of Northern Affairs, which are directly associated with the construction and operation and maintenance of air service infrastructure at the remote communities outlined in this proposal.

* Service to these points was suspended by the Ministry of Transport on June 30, 1975. Nevertheless, these communities have been included as part of the route system because it has been assumed that the suspension of Class 2 air service to these points, is of a temporary nature.

Private costs. Private costs refer to the direct operating costs of equipment incurred by a private air carrier in providing air service to the communities outlined in this proposal. Direct operating costs include, crew costs, fuels and oil, hull insurance, hull maintenance labour, engine maintenance labour, hull maintenance materials, engine maintenance materials, depreciation, and loan or rental charges.

Air transport needs. The air transport needs of the outlined communities are the current and forecast consumption of goods shipped by air to the communities and the current and forecast demand for passenger movement by air to the communities.

Existing landing facilities. Existing landing facilities in this study, are the current air infrastructure in place at the communities before new investments are made to provide additional capacity.

Existing operating equipment. The existing operating equipment refers to the aircraft currently being used on the specified route that serves the outlined communities on a scheduled basis. At present the operator, Midwest Airlines

Ltd. of Winnipeg, uses the De Havilland DHC-6, Twin Otter. Thus, this aircraft is considered representative of those used to currently service the air transport needs of these communities.

Growth in demand. The term, growth in demand, is used in the general sense to refer to the estimated probable requirement of each of the communities for goods and passenger services provided by the air mode. The forecast of growth in demand will be made for a five year period, from 1976 to 1981. The forecast projected air freight and passenger demands will be made on the basis of population growth at constant per capita levels of consumption.

Critical aircraft. The critical aircraft for an airstrip is the airplane with the largest cargo and/or passenger seating capacity that can legally be used to provide a unit-toll air service.

Cost efficient aircraft. Cost efficient aircraft are those aircraft which reputedly have lower direct operating costs per unit of output than the existing operating equipment. In this study the direct operating costs of the De Havilland Dash 7 and the Douglas DC-3 will be analyzed and

compared with those of the Twin Otter operating on the same route.

Monetary benefit. A monetary benefit is a reduction in the total cost of servicing the air transport needs of the group of communities outlined which comes about as the result of cost savings achieved by operating more cost efficient aircraft on the specified route joining the communities. The monetary net benefit is equal to the total cost of servicing the communities' projected air transport needs using existing landing facilities and existing operating equipment minus the total cost of servicing the communities' projected air transport needs using upgraded landing facilities and more cost efficient aircraft, plus the costs of upgrading.

Assumptions

The first assumption. The first assumption is that the data on freight volumes and passenger movements at each community are normal and representative of the community's air transport requirements.

The second assumption. The second assumption is that the growth in the demand for goods and passenger transport to each community, is constant.

The third assumption. The third assumption is that the rate of population growth is constant.

The fourth assumption. The fourth assumption is that patterns of consumption of the services offered by air transport do not change over the five year period.

The fifth assumption. The fifth assumption is that the level of consumption of air transport services at the communities is a function of population growth.

The sixth assumption. The decision to make additional investments to increase airstrip capacities is made purely on the grounds of economic efficiency.

The seventh assumption. The seventh assumption is that all of the air transport needs of each community are met from Winnipeg using the aircraft that is considered to be the critical aircraft for each community's airstrip or using an aircraft which promises to offer operating cost savings over those aircraft presently in service.

The eighth assumption. The eighth assumption is that any cost savings realized by the private air carrier because of a public investment in additional airport infrastructure, can be fully passed on to the consumers of air services.

THE DATA AND THE TREATMENT OF THE DATA

The Data Needed

The data necessary for the study may be discussed under three categories.

The first category of data are those which physically describe the physical and operational characteristics of the current air transport delivery system serving the communities outlined in this proposal. These data include the distances between the various communities, travel time between communities, present population of the communities, the volume of passengers and freight transported by air, the costs of operating and maintaining the airstrips at these communities, and the direct operating costs of the kind of aircraft presently serving the communities on a scheduled basis.

The second category of data are estimates of population growth rates at the communities under study, for a five year period, from 1976 to 1981. These data will be estimated on the basis of historical patterns and current population growth trends. Forecasts of air passenger and freight transportation demand will be based on population growth.

The third category of data is necessary to describe the physical and operating characteristics of an air transport

delivery system used to service the study communities, modified to accomodate more cost efficient aircraft than are currently being used. These data include (in addition to the type of information outlined in category number one) the costs of the additional investments required to increase the airstrip capacity at each community, and the direct operating costs of the proposed more cost efficient aircraft.

The Sources of the Data.

Physical & Operational Data. Mileage, distance and travel time information has been obtained from the Manitoba Flight Information Map Supplement¹ and the Transair System Timetable. Population data has been gathered from secondary sources. One of the most recent sources is from the Manitoba Northlands Transportation Study - An Economic Evaluation of Transport System Alternatives². The current operating and maintenance costs for the various airstrips has been obtained directly from the Airport Operations & Maintenance Division of the Department of Northern Affairs. Freight and passenger volume data have been obtained directly from airport activity

¹The Manitoba Flight Information Map Supplement.
The Department of Northern Affairs.

²Manitoba Northlands Transportation Study - An Economic Evaluation of Transport System Alternatives. Hickling Johnston Ltd., Toronto, Ontario, 1975. (unpublished report).

summaries compiled by the Airport Operations and Maintenance Division.

The direct operating costs of the Twin Otter (DTO) and the Dash 7 were obtained from Transair Ltd. of Winnipeg. The DOC's for the latter aircraft are the figures presented in a route study done by de Havilland Aircraft of Canada Ltd.¹ Direct operating costs of the DC-3 have been adapted from the Aviation Statistics Centre Service Bulletin (Vol. 7 No. 53, Sept. 1975)

Population Growth Data. Population growth estimates will be based on the information supplied by the Hickling Johnston Study.

Modified System Data. These data will be obtained from the same sources as data in the first category of data mentioned. The additional information regarding the costs of upgrading airstrips has been obtained from the Department of Northern Affairs, Engineering and Construction Services Branch.

¹Dash 7/Transair; Route Performance & Operating Cost Analysis, prepared by the de Havilland Aircraft of Canada, Limited, Downsview, Ontario, January, 1976

The Research Methodology.

The research methodology employed to analyze the problems presented at the outset of this proposal, is the Benefit-Cost method of analysis.¹ The treatment of all of the relevant data will be done within this framework.

The procedure involves the comparison of the total costs of operating alternative air transport delivery systems to the remote communities outlined in this proposal. Net benefits result when the operational costs of one system are less than those of another.

All benefits and costs will be discounted, for the five year planning horizon used in this study, at a discount rate equal to the cost of capital used in any additional investments to airstrip capacity. The cost of capital used in this study will be 10 per cent.

¹This study is not a benefit-cost analysis in the broad sense of the term. That is to say, benefit/cost ratios are not determined. Benefits and costs are implied in the computation of the cumulative net present value of cost outlays.

CHAPTER III

THE RESULTS OF THE ANALYSIS

A RE-STATEMENT OF THE METHODOLOGY

The first stage of the analysis involved the projection of air passenger and goods transportation demand for the period 1976 to 1981. The average growth rate in air cargo demand for the area corresponds closely with the population growth rate which is 3.5 per cent per annum. The population projections in this study are based on actual 1971 figures from the census of Canada. The growth rate in passenger traffic along this route has been observed to be approximately 7 per cent per annum.^{1. 2.}

The second stage of the analysis required the determination of all costs associated with the construction of additional capacity at the airstrips, the operation and maintenance of them and the delivery of passengers and goods.^{3.}

*10 ST. THERESA	D 2999'	572.00	449.00		Water to water, impractical to extend.

* Cost of NDB and lighting is included in the estimates.

To exclude these costs subtract \$50,000 to get the cost for Day VFR.

Note: Construction could be completed within two years.

Source: Province of Manitoba, Department of Northern Affairs, Engineering Services & Construction Services Division, B.E. Seppala, April 12, 1976.

The determination of the delivery costs of passengers and goods for the alternatives considered, involved a number of steps. The first step entailed the calculation of the number of trips that would be required to satisfy each community's annual air transportation needs.

Three aircraft with different freight and passenger capacities, the Twin Otter (D40), the DC-3 and the Dash 7, were compared - first assuming all the required cargo was delivered by one kind of aircraft and similarly, assuming all passengers to be delivered by each of the aircraft. The percentage of cargo or passengers delivered to a community on each circuit of the route has been assumed to be the same as each community's annual percentage share of the total amount of freight or passenger movement to communities on the route. Each plane commences from Winnipeg with the maximum possible passenger or freight payload (allowing for fuel and enough reserve fuel to fly to the designated alternate airport, in this case, Norway House). Weather conditions are assumed to be ideal with a zero wind factor. The next step in the determination of the cost

of delivery of both goods and passengers involved the calculation of the direct operating costs for each section of the route. This calculation involved the calculation of the total block time required to complete each section. Block time is a function of the air speed of the aircraft plus an allowance of approximately ten minutes for landing and takeoff manoeuvres. Turn around or ground time was not considered a cost because the air carrier usually does not include this time in the determination of direct operating costs of an aircraft. The direct operating cost per section, then, is equal to the block time used multiplied by the direct operating cost per hour. For the Twin Otter the D.O.C. per block hour is 265 dollars.¹ A figure of 540 dollars per block hour was used for the Dash 7² and 295 dollars per block hour was used for the D.C-3³. The total cost of delivery for

¹ Transair Ltd., Aircraft costing by Block Hour 1976, from the 1976 budget.

² Dash 7/Transair, Route Performance and Operating Cost Analysis, prepared by: The deHavilland Aircraft of Canada Ltd., Downsview, Ontario, January, 1976.

³ Statistics Canada, Aviation Statistics Centre, Service Bulletin; Vol. 7 No. 53, September, 1975

passengers and goods is equal to the cost per section multiplied by the number of trips necessary to reach the required output for any year during the 1976 to 1981 time period.¹

The final stage of the analysis required the determination of the cumulative net present value of all airstrip and delivery costs for each of the alternatives. The total cost for each year of the 5 year planning period are added together. Each community is done separately but in the same fashion. All costs are discounted at 10% per annum.² The rate is approximately the same as the Provincial Government's long term cost of capital. The cumulative net present value of all costs for each alternative, first for freight and then for passengers is presented in detail in tables C1 to C6 in Appendix C.³ A summary of the result is presented in Chapter IV.

¹ Please see tables B1 to B12 in Appendix B.

² Province of Manitoba, Planning Secretariat, conversation May, 1976.

³ Please note that the operations and maintenance costs of Norway House (\$127,131) have been used as a model of probable operating and maintenance costs at a Class "C" strip. Norway House was considered to be representative of the costs of a fully equipped "C" class strip of Northern Affairs Airport O. & M.

CHAPTER IV

THE DISCUSSION OF THE RESULTS

Operational Cost Savings & Disavings of Alternatives

1, 2 and 3 for Freight Output

Of the six communities for which complete construction cost estimates were available, four show that under the conditions set out in Chapter I, positive cost savings can be generated by upgrading existing facilities from Ministry of Transport Class "D" airstrips to Class "C" airstrips. This means that if all of the freight requirement of each of these communities was delivered using either a DC-3 or a Dash 7, the additional expense of greater airstrip capacity would be more than offset by the lower total cost of freight delivery in the five year period. At two communities, Norway House and God's Lake Narrows, the high cost of additional airstrip capacity would not be positively offset within the period 1976 to 1981. For these communities the analysis indicates that it would be more economical to use existing facilities than to upgrade. The disaving at Norway House would be greater if the \$330,000 necessary for a base course had been included in the additional construction costs.^{1 & 2}

¹ The finding of a disaving at Norway House is somewhat academic as the airstrip there already is a Class "C" licensed to M.O.T. standards. However, it should be that the Norway House airstrip is not a full Class "C" airstrip because zoning restrictions are in effect.

² A summary of these results appears in Table 6.

TABLE 6.

SUMMARY, OPERATIONAL COST SAVINGS/DISAVINGS BY ALTERNATIVE FOR FREIGHT OUTPUT¹

Cumulative Net Present Value of all Costs (in Dollars)	Berens	Poplar	Norway	Cross	Oxford	God's Lake	Red Sucker	Garden Hill	Ste. Therese	Little Grand
Alternative 1 (DTO)	5,324,215	2,281,631	3,070,636	2,242,532	4,041,865	2,527,297	2,533,980	2,808,465	1,426,911	4,716,589
Alternative 2 (DC-3)	4,274,361		3,098,154	2,096,353	3,250,741	2,623,418		1,752,406		
Alternative 3 (Dash 7)	3,609,927		2,734,713	1,988,183	2,928,694	2,530,923		1,630,773		
2 over 1	1,049,854		(27,518)	146,179	791,124	(96,121)		1,056,059		
Percent Saving/disaving	19.71		(.90)	6.51	19.57	(3.80)		37.60		
3 over 2	664,434		363,441	108,170	322,047	(92,495)		121,633		
Percent Saving/disaving	15.54		11.73	5.15	9.90	(3.52)		6.94		
3 over 1	1,714,288		335,923	254,349	1,113,171	(3626)		1,177,692		
Percent Saving/disaving	32.19		10.93	11.34	27.54	(.14)		41.93		

¹These results are true within the context of the assumptions made in Chap. II and at a 10 per cent discount rate for the period 1976-81. Some disavings could be reduced or eliminated by extending the pay-back period. The base data used in these calculations may be obtained in Appendices B & C.

Note: Bracketed numbers indicate disavings.

Operational Cost Savings & Disavings of Alternatives
1A, 2A and 3A for Passenger Output

All but one of the communities evaluated show that cost savings are associated with the construction of additional capacity at the airstrips. Again Norway House results appear to indicate that the economies of the larger more cost efficient aircraft would not be realized in the first five years of a construction program.¹

Priorization of Communities for the Purpose of
Construction of Additional Airstrip Capacity

The six communities for which complete construction cost estimates were available, were prioritized for the purpose of additional airstrip construction, according to percentage cost savings. This was done separately for passenger and freight output. The communities that may generate the highest cost savings over the given time period are given a higher order of preference so that they might be the first to receive additional airstrip capacity. The order of preference is similar for both the freight and passenger alternatives with the exception that God's Lake Narrows and Norway House appear in reverse order.²

¹ A summary of the results of the passenger output alternatives appears in Table 7.

² Please see Table 8.

¹ Percentage cost savings refers to the operational cost savings realizable by the upgrading of a "D" class airstrip to a "C" class airstrip in order to accomodate Class 2 regularly scheduled air service via DC-3 rather than DT0.

² Norway House and Garden Hill are already Class "C" airstrips except that there are some zoning restrictions in effect.

OTHER CONSIDERATIONS

The Frequency of Service and Economic Efficiency

There is a trade off between the generation of cost savings in the delivery of passengers and goods and the frequency of air service offered to a community. The benefits associated with the construction of additional airstrip capacity are derived entirely from the fact that larger capacity planes are able to deliver the entire compliment of community air services in less time and in fewer trips. It is probable that there are economies to be gained in the shipment of some types of freight because they can be marshalled and held over. This is less true of mail and perishable goods. The demand for air passenger movement obviously must be met when it occurs. The rationale, in the pursuit of economic efficiency, becomes not a question of more service but of less at a lower price. It is uncertain, particularly in the case of passenger service, to what degree the clients of a service would be willing to give up some convenience offered by the freedom of movement in favour of lower priced service.

From the point of view of the carrier, there is the awareness that in spite of their investment in a larger capacity more cost efficient aircraft, they run the risk of losing a portion of a market to operators with smaller aircraft that offer more frequent service.

The Distribution of Benefits

The operational cost saving criterion does provide the Province with a rational method for deciding how to allocate resources to existing communities within the airstrip development program. It does offer a way of prioritizing communities for further airstrip development within the confines of a limited budget, but there are two significant impediments which make the free operation of such a criterion difficult. The first impediment is that the benefits or operational cost savings which may occur as the result of airstrip upgrading, accrue first to the air carrier and not to the community or to the Province. The second impediment is that once additional airstrip capacity is built, the Province has no assurance that it will be fully utilized.

These problems arise because the Province and the air carriers are partners in an enterprise who each have differing objectives. The Province's concern in the delivery of air service to a community is to facilitate the desired level of service through the investment in infrastructure. The carrier while not providing the infrastructure must judge the market accordingly and invest in operating equipment which will return a reasonable profit.

The resolution of this latter problem may lie outside the scope of this practicum - in the procedure engaged in by the Canadian Transportation Commission and the air carriers with respect to the granting of operating licenses. Perhaps upgrading should not take place at an airstrip until both the Province and the prospective applicant are reasonably assured that a proposed service can be viable. Such assurance would come in part from more detailed information about the level of demand and the type of demand for air services at communities than is often available.

There are several mechanisms which might serve to help pass on the benefits of reduced operating expenses to the local community and/or the province. The authority

of the Canadian Transport Commission to approve or disapprove passenger fares and freight rates is one way. The entry of new competition into a route is another. The use of landing fees by the airstrip operator, in this case the Province is still another possible way of transferring some of the operational cost savings on to shippers and consumers.

Patterns of Demand

The purpose of this practicum is to offer a rational economic criterion to be of assistance in the making of decisions relating to the upgrading of remote airstrips. It is not intended as a route study and as such it can not realistically be concluded categorically that the DC-3 or Dash 7 are the best aircraft to service the route.

It was assumed that the pattern of demand for passenger and freight services by air is no different from day to day than it is on an annual basis. This is true on average. The simplification was made because airport activity summaries do not record the origin of passenger and cargo flights. So for the purpose of uniform comparison, Winnipeg was assumed to be the origin of all flights and consequently all the air transport needs of each community would be satisfied

from Winnipeg.

In actual fact the air transport demand along the route on a scheduled basis probably fluctuates considerably from day to day and between seasons. In order to choose the optimum plane for the route, the same methodology used in this study could be applied but more detailed information concerning the market share of each carrier, the freight to passenger ratio on trips and variations in the quantities of cargo and passengers transported over time would have to be known.

CHAPTER V

CONCLUSIONS AND RECOMMENDATIONS

CONCLUSIONSThe Practicality of the Model

The use of the benefit-cost method of analysis and the application of the operational cost saving criterion, within the benefit-cost framework, does fulfill the major objectives of this practicum as stated in Chapter one.¹ The approach has merit in the solution of the management problem outlined - ie, the upgrading of remote airstrips within a limited budget. Where other considerations do not take precedence over economic efficiency, the approach is a rational and administratively feasible way of allocating economic resources.

The extent to which this application of the benefit-cost method is actually used in airstrip upgrading decisions by the Department of Northern Affairs is subject to at least three reservations; the realization

¹ Chapter I, The Statement of the Problem - P. 4
and The Definition of terms, practical model - P. 7

of a transfer of the benefits of larger capacity airstrips from the air carrier(s) to the clients of an air service or the Province, the willingness of clients of an air service to sacrifice some frequency of service for some cost reductions in the transportation of passengers and goods and the assurance that upgraded strips can be fully utilized by the introduction or expansion of improved air services.

The two former concerns are matters of judgment on the part of the government manager for they have political implications that go beyond the upgrading issue. With regard to the latter concern, the advent of more detailed airport activity reports and greater liason between the provincial government and air carriers proposing to offer improved air services to communities in Northern Manitoba can do much to reduce the risk of constructing airstrips which may prove to be over capacity.

The Limitations of the Study

One major objective of this study has been to illustrate that the upgrading issue (in relation to remote

airstrips in Manitoba) is capable of being reduced to a management problem - one from which realistic solutions can be derived through systematic examination. In order to do this it should be pointed out that simplifications were necessarily made. Obviously some constraints were placed on the number of possible alternatives investigated and some issues which have a bearing on the provision of northern air services but which were peripheral to the immediate problem under study, had to be omitted.

The choice of aircraft to be evaluated was arbitrarily limited. There are no doubt, several other types of operating equipment that could be compared. A five year payback period was chosen for two reasons - first a shorter period reflects the need for early, tangible returns on new public investments and secondly, because the reliability of predictions decreases the further they are removed from the present. A market rate of discount as opposed to a social rate of discount was used. The evaluation of a wider range of alternatives under a variety of different assumptions concerning the rate of growth in demand for certain types of air services, the length of the planning period, the magnitude of the discount rate etc. certainly would be useful.

In this study, population is used as the sole determinant of passenger and freight demand by air. However, changes in the volume of air traffic between communities may also be a function of economic development, personal incomes, the degree of community self-sufficiency in terms of reliance on the natural resource base for the provision of needs and the existence of other transportation modal linkages. Where these kinds of data are available they should be used in order to improve the predictive qualities of the model for forecasting future air traffic demands at communities under study.

There are a number of important issues which would require an entirely different methodological framework than the one used in this study, in order to be evaluated. They are political or legal and regulatory in nature. For example, the development of criteria to govern initial public investment in airport infrastructure and the definition of minimum construction standards for airstrips are questions where the opinions of the responsible parties are at variance. It became apparent during the course of this study that there is a train of airport support services that follows in the "wake" of the issuing of a license to provide particular classes of air service. There is confusion and disagreement about what services are to be offered with each class of air service, which support services are essential, and what agency (or agencies) is legally and financially responsible for the provision of these support services.

RECOMMENDATIONS

The first recommendation is that the possible merits of greater provincial involvement in the approval of improved levels of commercial air service at remote communities be investigated further. This recommendation does not come about as the direct result of the analysis

done in this study but arises from the belief that because the responsibility for the provision of air services to remote communities is so divided that co-operation between the different concerned parties (The Ministry of Transport, The Department of Northern Affairs and the private air carriers) that a greater degree of co-operation is both desirable and essential.¹

The second recommendation relates to the collection of data for The Department of Northern Affairs airport activity reports. It would be extremely valuable in future studies of the air transportation system in Northern Manitoba if the reports recorded the origin of flights as well as the destination, the name of the commercial operator and type of airplane, according to manufacturer and model. Such measures would simplify the conduct of future studies by facilitating the analysis of the actual economic feasibility of offering improved air services over specified routes using various types of aircraft to carry out service.

¹It should be emphasized that this is a recommendation for further study.

APPENDIX "A"AIR TRANSPORTATION POLICY AND STRATEGY
FOR REMOTE COMMUNITIES IN NORTHERN MANITOBA

I. POLICY - to provide facilities for 12 months air transportation (VFR) in all northern communities of 100 or more persons without access by road.¹

II. STRATEGY

1) To provide key potential regional centres with airports capable of handling scheduled passenger and freight aircraft on a 24-hour basis during all seasons.

Facilities provided would include:

- . graded, gravel runways
- . beacon and runway lights
- . radio equipment
- . terminal building with weather facilities
- . warehouse facilities
- . snowplowing, dragging and fire-fighting equipment.

¹ Wherever possible, airstrips and associated facilities would be located in close proximity to float-plane bases in order to serve both types of aircraft and to permit easy transfer of both passengers and freight from one to the other.

Upon completion, passenger fares would be considerably lowered, scheduled service more dependable and air freight costs could become more competitive with tractor, train or truck hauling over winter roads along with greater frequency (and therefore less storage) and less damage to cargo.

Priority centres for airstrips are:

- . Norway House
- . Garden Hill.

This would link the central and eastern, northern Manitoba communities with both Winnipeg and Thompson on a scheduled and lower cost basis.

2) To provide centres without road access with 500 or more population with airstrips having the following facilities:

- . graded, gravel runway, small terminal building and warehouse;
- . radio equipment available through Department of Mines, Resources and Environmental Management field office;
- . snowplowing, dragging and general maintenance arrangements with local authorities.

These airstrips would be operational at all times of the year during daylight hours for visual flying.

They would facilitate scheduled passenger and freight operations hereby reducing access costs and general costs of living without abnormally high per capita sunk capital costs. Access would be more available, in particular to either the regional airports or to the mainline airports of Thompson, Flin Flon, The Pas, Lynn Lake, Churchill and Gillam.

Priority airstrip locations are:

- | | |
|-----------------|-----------------------|
| . Beren's River | . Brochet |
| . Cross Lake | . Moose Lake |
| . God's Narrows | . Little Grand Rapids |
| . Oxford House | . Pukatawagan |
| . Nelson House | . Ste. Therese Point |
| . Leaf Rapids | |

3) To provide centres without road access with 100 or more population with a graded sand or clay landing strip with light gravel. Existing landing strips of this quality have been in fairly regular use in 23 northern communities over the past year. While not as dependable as graded gravel in all weather conditions, they provide for economical and quite dependable service by lighter aircraft¹ at relatively low capital cost. As well, many are located on or

¹ Twin Otter type or smaller

near scheduled routes of larger aircraft and would serve as emergency landing sites.

Priority locations for landing strips are:

- . Poplar River
- . Shamattawa
- . Split Lake
- . South Indian Lake
- . York Landing
- . Bloodvein
- . Thicket Portage
- . Pikwitonei
- . Ilford
- . Red Sucker
- . Sherridon

4) Access to and from other communities (many are under 100 population), including those nearby locations served by the above (e.g. Wasagomach - population 204) will continue, at least until the priority projects are completed, to be served by water, over ice in winter, by float or ski-equipped aircraft, or by helicopters strategically located during freeze-up and thaw for emergency purposes.

5) To make provision for airstrips for exploration and development purposes in northern Manitoba. These airstrips would be authorized by the provincial government but financed by the exploration or development company involved. They would be available to the general public on an emergency basis only and upon completion of

the exploration or development project the control could revert to the provincial government.

III. JUSTIFICATION

- . residents have the same right of access to opportunities and services (particularly those publicly sponsored) as all other citizens.
- . road access to these communities is extremely expensive.
- . capital costs of high quality airports at all locations is expensive.
- . the level and frequency or intensity of service varies by community size and role.
- . Wheel equipped aircraft are faster and more efficient than those equipped with floats or skis.
- . tractor trains for freight hauling are slow, unpredictable, relatively inefficient and suited only to certain types of cargo.
- . scheduled passenger service would reduce transportation costs to residents, and also to the public generally when compared to the present cost of charter float or ski service.
- . access to health and medical facilities would be greatly improved, particularly during periods of freeze-up and thaw.

- . improved real physical access, along with, improved communications, would provide a basic foundation for greater understanding of the larger society; opportunity horizons could be broadened; and a major physical constraint to mobility (either of a permanent or of a temporary "testing" nature) would be removed.
- . considerable employment would be created during the construction stage with some continuing employment during operations: not only would this provide job and income opportunities; it would provide an environment for training or orientation (along the lines of the Manpower Corps Program) that would further enhance long term employability of those involved.
