Abstract

Cellulosic ethanol production is mainly described as an anaerobic process. Through use of aerobic selective pressure, using inoculate from samples taken from a farm in South-Eastern Saskatchewan, Canada, we were able to create highly cellulolytic aerotolerant enrichments which produced both hydrogen and ethanol. We were able to recreate this highly cellulolytic aerotolerant phenotype using *C. thermocellum* DSM 1237 and one of the *Caldibacillus debilis* strains isolated from the aerotolerant enrichments, strain GB1.

Caldibacillus debilis GB1 is a thermophilic facultative anaerobe. *C. debilis* GB1 displayed a physiology distinct from that of the type strain Tf which is an obligate aerobe. Under oxygen limiting conditions, both GB1 and Tf produce end-products lactate, acetate, formate and CO_2; however, GB1 alone produces ethanol.

A key feature necessary for aerotolerant growth of the co-culture with *C. thermocellum* was the capacity of *C. debilis* GB1 to grow both aerobically and anaerobically. In order to characterize GB1, we sequenced and annotated the genome then used high throughput proteomics to characterise the protein expression changes between aerobic and anaerobic metabolism. We found *C. debilis* GB1 has typical mixed fermentation pathways and aerobic/anaerobic regulation similar to those found in *E. coli* K-12 and *B. cereus*.

In order to explain the lack of ethanol production in the type strain, *C. debilis* Tf, we did a genomic comparison of both strains Tf and GB1, focusing on the genes concerning pyruvate metabolism. In particular, there were amino acid changes in the

aldehyde-alcohol dehydrogenase ADHE that could lead to inactivity in strain Tf. This genomic evidence, plus Tf having physiology consistent with an *adhE* deletion mutant in the closely related *Geobacillus thermoglucosidasius,* leads us to propose that the *adhE* gene is either differently regulated or inactive in *C. debilis* Tf.

From our work, we showed that *C. debilis* GB1 allowed us to further define and characterize the physiology of the genus *Caldibacillus*, find a new aerotolerant mode of mode of Consolidated bioprocessing using *C. thermocellum*, and further understanding of aerobic/anaerobic regulation in thermophilic facultative anaerobes.

Acknowledgements

Thank you to my advisor and mentor Dr. Sparling for giving me guidance, support, and the opportunity to do this research.

Thank you to my supervisory committee members: Dr. Brassinga and Dr. Cicek

Thank you to collaborators who offered guidance and support: Dr. Levin, Dr. Stott, and Dr. Fristensky.

Thank you to those guided and helped me with the Omics work: Peyman Ezzati, Xiang Li Zhang, Vic Spicer and Dr. Krokhin

Thank you to my friends and lab mates: Tobin Verbeke, Tom Rydzak, Marcel Taillefer, Alan Froese, Charushi Panditharatne Carlo Carere, Umesh Ramachandran, Rumana Islam, Nathan Wrana, Valery Agbor, Jilagamazhi Fu, Ryan Sestric, Riffat Munir, Tatiana Kozlova, Parveen Sharma, Maryam Mirzaie, Chris Dartiailh, Warren Blunt and Elsie Jordaan, as well as many others that are too numerous to mention.

Thank you to Ariadne Valadares who suffered through so much proof reading for me.

Dedication

To my parents, who never stopped believing in me.

Chapter 1: Developing Consortia for Ethanol Production from Consolidated Bioprocessing

1.1. Introduction and Justification for Use of Consolidated Bioprocessing

The establishment of a sustainable and environmentally conscious economy is essential for combating the effects of man-made climate change. Biofuels are an obvious and logical replacement for fossil fuels given that they can create a closed-carbon-loop, resulting in reduced Green House Gas (GHG) emissions (DeCicco *et al.* 2013). One biofuel production process that looks particularly attractive is Consolidated Bioprocessing (CBP). A one-step hydrolysis and fermentation process, CBP uses lignocellulolytic substrates (e.g. wood, and wood waste, straw and other structural residues from food crops) to create ethanol or hydrogen. Currently, this process is not cost competitive, but if the process could be done effectively, it is projected to be one of the least expensive forms of ethanol production (Lynd *et al.* 2005, Olsen *et al.* 2012, Jouzani *et al.* 2015). In order to make CPB work as an economically viable process, we need to study multiple modes of operation, with different and unique bacteria in order to find the most economically viable production conditions (Jouzani *et al.* 2015, Olson *et al.* 2015). At this time, CBP is not operating at its theoretical maximum economic efficiency (Lynd *et al.* 2005; Jouzani *et al.* 2015). Making CBP financially beneficial is required before the adoption of this technology becomes sufficiently attractive to potential users. It is not clear whether this process can be optimized using a single organism, or require several organisms working in concert. It is also unclear whether there may be further improvements

from not yet discovered organisms or consortia (Jouzani *et al.* 2015). There is intense research into CBP using both pure cultures (Jouzani *et al.* 2015) and co-cultures consisting of cellulose degraders partnered with non-cellulolytic organisms (Hann *et al.* 2015). In order to further develop CBP, it is important to continue to bio-prospect, and to characterize novel organisms and organism combinations under conditions that may encourage CBP. As we characterize the physiological aspects of these organisms, it is also important to apply high throughput omics techniques. These techniques will help build the foundation of knowledge required to generate new hypotheses, as well as allow us to make inferences about other organisms and their abilities in order to fully explore all CBP options. (Olson *et al.* 2015).

1.2. The Need for Biofuels in 2016

Non-renewable fuels are a major producer of GHG emissions. Not only do they contribute to climate change, but the manipulation and burning of non-renewable fuels contributes a plethora of additional pollutants such as sulfur and BTEX (benzene, toluene, ethylbenzene, xylene) hydrocarbons (Kampa *et al.* 2008, Demirbas *et al.* 2009). Transitioning to renewable sources of fuel is an essential step in minimizing future increases of net GHG production as they can offset the CO_2 produced through combustion (DeCicco *et al.* 2013), theoretically decreasing net CO_2 emissions, as shown in Figure 1.1.

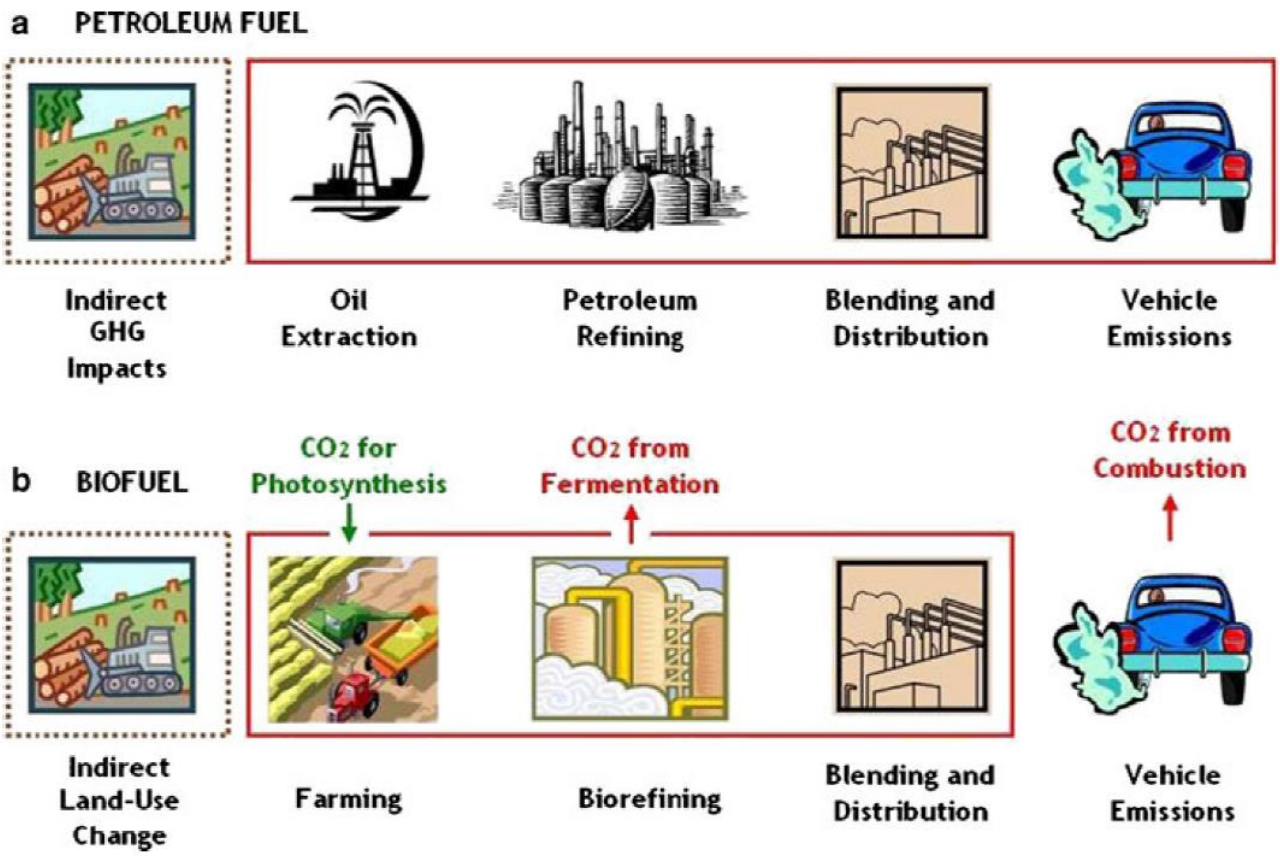

Figure 1.1. Carbon emission diagram where the CO_2 is both the input and output offsetting net CO_2 emission when using biofuels (b) when compared to petroleum fuel (a). (Source: DeCicco *et al.* 2013)

Due to their potential environmental and economic benefits, biofuel and biofuel co-product production is currently a highly active area of research with major interest involving, but not limited to: production of bio-oils (Koutinas *et al.* 2014), bioalcohols (Wheals *et al.* 1999), and bioplastics (Noda *et al.* 2010). In order to entice large private-sector entities to begin mass production of biofuels, an emphasis on the economic benefits is necessary. There are many examples of biofuel producing industries operating in an economically viable capacity (Wang *et al.* 2012, Koller *et al.* 2010, Olagunju *et al.* 2008). Bio-oils are well established at the economic scale, and have been shown to be economically viable with reliance on agricultural crops such as canola or palm plants (Kwon *et al.* 2015, Johari *et al.* 2015). However, due to the displacement of food or feed producing crops, such practices are being called into question. There is also intense research into bio-oils from microalgae, which can be grown anywhere in a controlled environment, and do not displace land to the same degree as crops (Gao *et al.* 2015). Bioplastics such as PHA (polyhydroxyalkanoates) and PHB (polyhydroxybutyrate) are both mass-produced and intensively researched (Koller *et al.* 2010). They utilize a variety of organic substrates such as sugar, glycerol, and acetate, and produce a wide selection of bioplastics depending on substrate, organism, and media condition (Koller *et al.* 2010). Ethanol and mixed solvents [acetone butanol plus ethanol (ABE)] are two prominent examples of bioalcohol production resulting in profit (Chen *et al.* 2015, Kong *et al.* 2015). Historically, food products such as wheat and barley have been the prominent substrates used in bioalcohol production, but there has recently been more research done in non-food bioalcohol production, such as lignocellulose to avoid ethical

concerns about increasing food prices due to crop displacement and to further increase total biofuel productivity by expanding substrates (Christian *et al.* 2010, Jouzani *et al.* 2015,).

There is room for further developments and increases in economic viability on several fronts in bioalcohol production using CBP (Lynd *et al.* 2005, Jouzani *et al.* 2015). The creation of biofuels and related co-products is a dynamic process that can utilize and create its own distinct waste streams. Efficiently utilizing every organic waste stream for cost effectiveness is important. Many of these processes create low value, high volume outputs, but there is potential to link these processes to the production of high value, low volume products such as resins from lignin (Demirbas *et al.* 2009) or high value bioplastics for specific purposes (Chen *et al.* 2009). Currently, the study of biofuels is a highly active area of research for both economic and environmental reasons, and there is a strong political encouragement to make biofuels displace fossil fuels. To what extent this is possible remains unclear (Solomon *et al.* 2015. Doshi *et al.* 2016, Chen *et al.* 2016).

1.3. Ethanol and Hydrogen

Ethanol and hydrogen are common microbial biofuels (Balat *et al.* 2011, Levin *et al.* 2004) produced by a wide range of microorganisms, and as such are a common focus of study within the realm of biofuels (Jouzani *et al.* 2015, Ghimire *et al.* 2015). Chemically, hydrogen and ethanol offer several advantages and disadvantages for use as biofuels. In vehicles for instance, hydrogen can be 60-75%

efficient through conversion directly into electricity by proton exchange membranes (Lamy *et al.* 2016), giving it a distinct advantage over internal combustion engines that typically have an upper limit of ~37% efficiency (Ferguson *et al.* 2015). However, hydrogen is considered difficult to work with due to its chemical properties such as causing hydrogen embrittlement (Daw *et al.* 1983). It is also a small molecule prone to leaking when being stored or transported using piping (Okazaki *et al.* 2003). The use of hydrogen through conventional combustion makes it less competitive than other flammable gases such as methane or propane, gases with better compressibility factors then hydrogen, which significantly reduce the cost of storage (Das *et al.* 1996). Up until now, little infrastructure has been developed around hydrogen as a fuel, making consumer adoption difficult without further investment in compatible infrastructure (Singh *et al.* 2015). There is still active research into hydrogen production, but it may be less favored over other biofuel types (Singh *et al.* 2015).

Ethanol production is appealing because it can use already existing infrastructure and established protocols for production allowing easy adoption by the consumer (Chen *et al.* 2015). The fact that ethanol is a liquid fuel that can be integrated into existing fuels, such as gasoline, directly by blending (Wheals *et al.* 1999) gives it a significant advantage as progress can then be incremental. For example, fuel for a car could vary anywhere from 1% to 100% ethanol (Coelho *et al.* 2006, Yüksel *et al.* 2004). While the physical properties of ethanol may be less than ideal compared to other biofuels, the relative simplicity of production from familiar processes, and integration into existing gasoline infrastructure, make it an ideal start point for biofuel production (Yüksel *et al.* 2004, Sarkar *et al.* 2012). A single ethanol

production factory can produce millions of liters of ethanol per year making ethanol production a consumptive process with regard to inputs. In order to meet demand the amount of ethanol produced will have to increase further. Choosing the right feedstock for the process is essential, as the substrate will be needed in large quantities (Sarkar *et al.* 2012). Using an inexpensive, plentiful substrate would greatly benefit the overall process cost and strengthen the economic case for ethanol production (Sarkar *et al.* 2012). Moving away from old technology, designated first generation biofuels, which can rely on relatively expensive ingredients, such as wheat, corn or other food crops, is absolutely essential in order to create inexpensive, environmentally friendly, ethical biofuels (Lynd *et al.* 2005, Jouzani *et al.* 2015).

1.4. First, Second, and Third Generation Biofuels

In an effort to develop ethanol, several different approaches are generally considered and designated as first, second, and third generation. First generation biofuels are typically defined as being derived from easily hydrolyzed starches, usually grain feed stocks, fermented using yeast (e.g. *Saccharomyces cerevisiae*) to produce ethanol (Lynd *et al.* 2005. Olson *et al.* 2012, Jouzani *et al.* 2015). A prominent example of this is wheat and corn ethanol production in the United States (U.S.) (Pimentel *et al.* 2005). First generation biofuels are produced from food crops, using processes derived from the brewing and distilling industry. Some would argue that first generation biofuels inflate food prices and creating a moral dilemma, an example of this is corn subsidies for biofuel in the U.S. (Piesse *et al.* 2009). Inflated

food prices could contribute to starvation and malnutrition in low-income families of poor countries (Christian *et al.* 2010).

Second generation biofuels are derived from lignocellulosic feed-stocks that undergo some form of chemical, physical, or biochemical treatment. This results in the hydrolysis of cellulose into sugar monomers that can be fermented by yeast using more traditional brewing and distilling methods to produce ethanol (Lynd *et al.* 2005, Jouzani *et al.* 2015). An example of second generation biofuels is the use of enzymatically hydrolysed corn stover (Humbird *et al.* 2011).

Third generation biofuels would be derived from the simultaneous hydrolysis and fermentation of a lignocellulosic substrate using an organism or several organisms together that are capable of simultaneous cellulose hydrolysis and fermentation. Due to the possibility for the third generation of biofuels to be a one step process, often referred to as consolidated bioprocessing (CBP), third generation biofuels are seen as providing the lowest costs of operation. However, that potential has not yet been realized, and as such CBP remains an active area of research (Lynd *et al.* 2005, Olson *et al.* 2012, Jouzani *et al.* 2015).

1.4.1. Feedstock for Consolidated Bioprocessing

A recurring theme in production of biofuel and biofuel co-product production is the importance of using low cost feed-stocks that require minimal pre-treatment. Low cost and easy to integrate feed-stocks can come from sources such as marginal lands or waste streams from other process (Lynd *et al.* 2005, Jouzani *et al.* 2015). For

ethanol or hydrogen, as stated previously, lignocellulose is particularly attractive as there are known organisms that are both highly cellulolytic and produce ethanol and hydrogen as end products such as *Clostridium thermocellum* or *Caldicellulosiruptor bescii* (Jouzani *et al.* 2015).

Another factor is the size and geographic availability of these feedstocks. For ethanol production the required output can be in the millions of liters of throughput per year for a single site meaning inputs will be very large, as such transportation costs, both in financial and environmental terms, become a factor (Lynd *et al.* 2005). To be attractive as a biofuel substrate, a lignocellulosic feedstock must meet the following criteria: high abundance, wide geographical availability, low cost of production or recovery from a waste stream, and potential for value added co-products derived from lignin (Lynd *et al.* 2005, Jouzani *et al.* 2015). Some notable examples of feedstocks that have been considered are recycled paper/cardboard, pulp and paper industry wastes, straw, switchgrass, hemp, and wood chips (Moreau *et al.* 2015, Schuster *et al.* 2013, Agbor *et al.* 2014, Horisawa *et al.* 2015).

1.4.2. Lignocellulosic Composition

The primary constituents of lignocellulose are lignin, cellulose, and hemicellulose, which for a substrate like plant biomass make up roughly 20%, 40 %, and 30% respectively (Agbor *et al.* 2014). Cellulose is composed of glucose molecules in β1-4 linked chains while hemicellulose is typically comprised of a xylose-linked backbone. The overall goal of CBP is conversion of cellulose, which

represents the bulk of hydrolysable biomass, and hemicellulose polymers into sugar monomers and simultaneous fermentation into biofuels. The hydrolysis of the cellulose (typically into cellobiose or glucose) is considered the crucial rate-limiting step, and is a core feature of research into biofuel production from lignocellulosic substrates (Lynd *et al.* 2005). Furthermore, it is essential to hydrolyze and ferment all the sugars. For instance, hemicellulose is comprised typically of a xylose back-bone that can be decorated with many different sugars such as arabinose and mannose (Olsen *et al.* 2012). Depending on the organism, it may not be able to fully use the hydrolysate or fully hydrolyse the lignocellulose sugar components. This is an issue observed in C. *thermocellum.* While it is highly cellulolytic, it is unable to use pentose sugars derived from hemicellulose hydrolysis (Lynd *et al.* 2005), causing a significant draw back. Although some of the sugars contribute to <1% of the possible total sugars, this can be economically significant at scale. The third component is lignin, which is a non-repeating polymer comprised of various different subunits including *p*-coumaryl alcohol, coniferyl alcohol, and sinapyl alcohol (Agbor *et al.* 2014). Under conditions relevant to CBP, lignin is not fermented into bio-products to any great extent and can be toxic to cells especially when solubilised (Parisutham *et al*. 2014). It appears to be potentially profitable to make ethanol from the cellulose and hemilcellulose (Lynd *et al.* 2012); however, the addition of a high value product such as a lignin derived resin or biofuel related co-product would indeed greatly increase the economic viability of the entire process.

1.5. Typical Mixed Acid Fermentation of Bacteria and Ethanol Production

While the process of ethanol production from simple sugars using yeast is a well-known and efficient process, yeast do not fulfill the other demands of CBP using lignocellulosic substrates. Yeast do not naturally express cellulases and usually do not co-utilise xylose, glucose, and/or cellobiose (Wei *et al.* 2015). Bacteria that produce ethanol typically show lower ethanol efficiency, total yield, and tolerance when compared to yeast such as *Pichia stipites* or *Saccharomyces cerevisiae* (Olson *et al.* 2015), with the notable exception of *Zymomonas mobilis*, which is used due to its ability to ferment xylose efficiently to ethanol (Scopes *et al.* 1986). Bacteria commonly produce ethanol in the context of mixed acid fermentation producing some combination of lactate, acetate, formate, ethanol, CO_2, hydrogen, and succinate (Förster *et al.* 2014). This type of metabolism is seen in a wide variety of organisms, notably *Clostridiaceae, Enterobacteriaceae,* and *Bacillaceae* (Penning *et al.* 2006, Rachman *et al.* 1997, Nakano *et al.* 1997). Many of the bacteria aggressively studied in regards to biofuels produce some permutation of mixed acid fermentation, such as *C. thermocellum* (outlined in figure 1.2), *Caldicellulosiruptor spp.*, *Thermoanaerobacter spp.* and *Geobacillus thermoglucosidasius.* With ethanol production being the goal, it makes sense to characterize potential CBP candidates for end-product production looking for organisms that have high ethanol output, and do not produce competing end-products such as H_2 or lactate (Olson *et al.* 2015). Olson *et al.* (2015) compare pyruvate metabolism and possible modes of ethanol production, which are inextricably linked to their mixed acid production profile. While organisms

have been studied and modified to produce high yields of ethanol in organisms that are innate ethanol producers, Olsen *et al.* (2015) state that current work moving forward should focus on three things: i) increasing volumetric productivity; ii) increasing total titre; and iii) sufficiently understanding the high ethanol producing gene complement to be able to transfer it to low/non ethanol producers.

How an organism determines its end-product ratios can be quite complex and will be determined by the: i) gene complement; ii) regulation at the transcriptional, translational, and enzymatic level; and iii) intracellular concentrations of metabolites and co-factors. An example of this is ethanol production in members of the genus *Thermoanaerobacter*, as discussed by Verbeke *et al.* (2013), and their different *adh* genes. It appears based on the species analysed that they have between 5 and 9 annotated *adh* genes. There are also distinct types of alcohol dehydrogenases that have been characterized: *adhA*, *adhB*, and *adhE*. The propensity to synthesize ethanol through a given *adh* is in part determined by whether they are NADH-dependent or NADPH-dependent, as well as the intercellular concentration of each co-factor. The intercellular concentration of NADPH and NADH can in turn change depending on what pathways are used to break down a substrate and the composition of the substrate. It is absolutely essential to understand ethanol production at a systems level in order to manipulate physiological conditions and, thanks to genetic engineering tools, the gene complement of a strain in order to enhance ethanol production.

1.6. Organisms for Potential Use in Consolidated Bioprocessing

In order for a culture to be capable of CBP from lignocellulose substrates, it must simultaneously be cellulolytic and produce biofuels. Many organisms are studied in relation to CBP including *Caldicellulosiruptor spp.* (Chung *et al.* 2015), *C. thermocellum* (Biswas *et al.* 2015), *C. phytofermentans* (Zuroff *et al.2013), C. cellulolyticum* (Petitdemange *et al.* 1984), as well as many others (Olsen *et al.* 2012, Jouzani *et al.* 2015). Not only are these organisms studied individually, but also in combination with other non-cellulolytic partners (Jouzani *et al.* 2015).

1.6.1. *C. thermocellum* Role in Consolidated Bioprocessing

Among the most studied organisms for consolidated bioprocessing of lignocellulosic substrates is *C. thermocellum*, a thermophilic cellulolytic strict anaerobe capable of mixed acid fermentation and hydrogen production (Lynd *et al.* 2005, Olsen *et al.* 2012). *C. thermocellum* has shown high rates of cellulose hydrolysis from a variety of cellulosic substrates (Lynd *et al.* 2002, Jouzani *et al.* 2015), making it an attractive candidate for use in CPB. A property of *C. thermocellum* that allows for such a high cellulose degradation rate is an external organelle known as the cellulosome (Beguin *et al.* 1998), which acts as a scaffold for cellulolytic proteins, as well as proteins to bind to cellulosic substrates to enable a close interaction between the cell and substrate.

C. thermocellum has been studied extensively for both its ethanol and hydrogen production. While *C. thermocellum* is a major model organism, it is not a

perfect fit for CBP for ethanol as there are several drawbacks, namely: i) lack of aerotolerance; ii) inability to degrade many sugar substrates found in lignocellulose including pentoses; iii) poor ethanol production and tolerance, and iv) production of a range of fermentation products including amino acids (Ng *et al.* 1977, Lynd *et al.* 2005, Papanek *et al.* 2015, Biswas *et al.* 2015). Furthermore, *C. thermocellum* can be rather difficult to maintain in pure culture (Mori 1995), partially due to its poor inoculation efficiencies and intolerance to redox perturbation (Ng *et al.* 1977).

C. thermocellum displays a rather typical mixed acid fermentation profile (Figure 1.2) with major end-products: ethanol, lactate, formate, acetate, H_2, CO_2, and formate being produced. This makes *C. thermocellum* of potential interest in both hydrogen and ethanol production process (Levin *et al.* 2006, Rydzak *et al.* 2015). Efforts to enhance ethanol production have been successful, but can also lead to other unintended consequences as these pathways form a complex network of interactions. There are several examples of this: i) the removal or deactivation of the hydrogenases decreases H_2 and increases ethanol production, but also decreases the tolerance of *C. thermocellum* to ethanol due to redox balancing issues (Biswas *et al.* 2015), and ii) the elimination of formate to direct more electrons toward other end-products by deleting pyruvate formate lyase genes does increase ethanol production, but the elimination of formate production hinders biosynthesis (Rydzak *et al.* 2015). As the major non-beneficial end-products are eliminated, the cells begin to produce previously minor end-products in greater quantities leading to the synthesis of products such as amino acids, pyruvate, malate, fumarate, isobutanol, and butanediol (Rydzak *et al.* 2015).

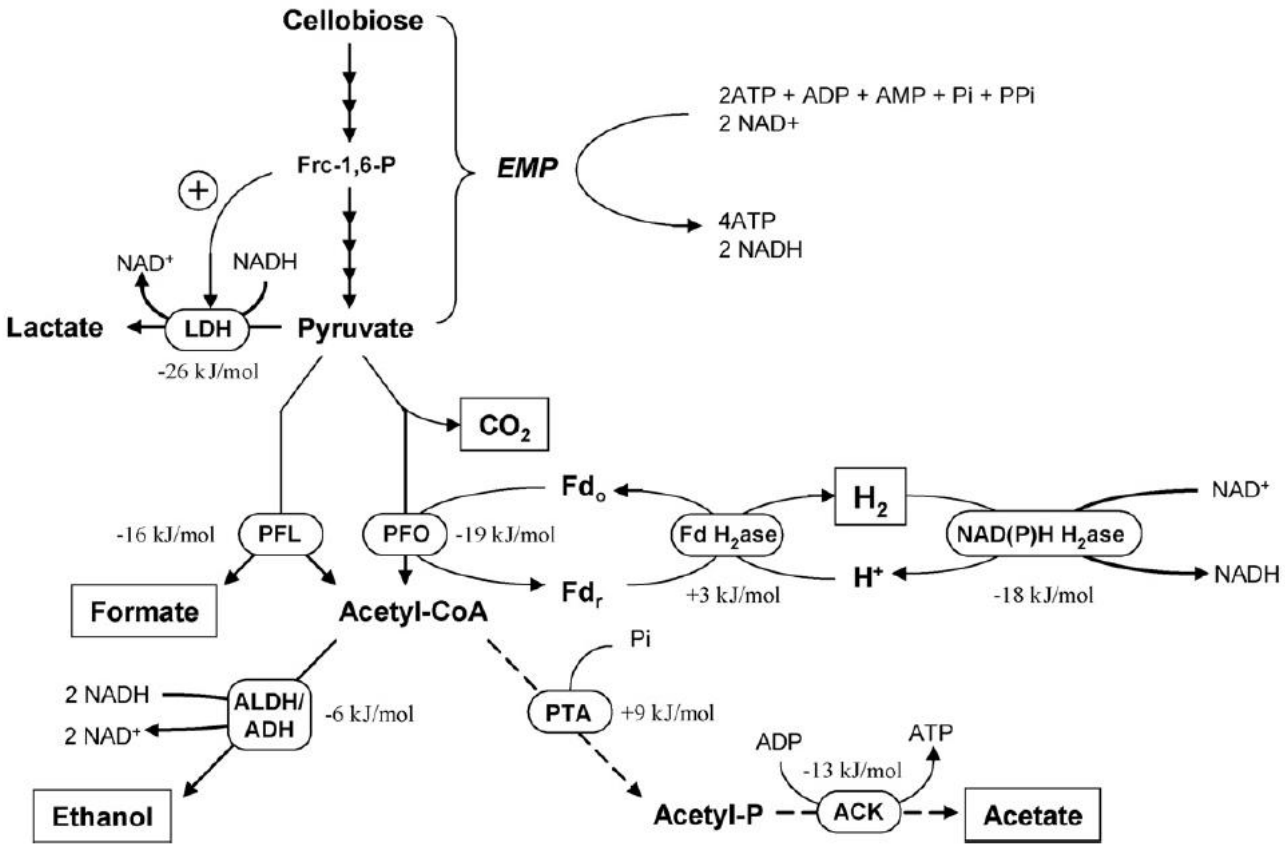

Figure 1.2. Pyruvate metabolism leading to mixed acid fermentation in *C. thermocellum* (source: Rydzak *et al.* 2009)

1.6.2. *Caldicellulosiruptor* Role in Consolidated Bioprocessing

Many *Caldicellulosiruptor spp.* have the ability to simultaneously degrade and use cellulose and hemi-cellulose (Blumer-Schuette *et al.* 2011). Several have been sequenced and analysis has shown that they vary in their hydrolytic abilities. Cellulolytic members of this genus have their own unique benefits such as being hydrogen producers, wide substrate utilization range, and complete use of sugars in lignocellulose (Abreu *et al.* 2013). There are drawbacks as well, such as requiring strictly anoxic conditions and typically only producing small amounts of ethanol (<=40% theoretical maximum) (Cha *et al.* 2013). One of the most prominent differences between *Caldicellulosirupter sp.* and *C. thermocellum* is the presence of a cellulosome in the latter organism. Its presence is both an advantage and disadvantage as the cellulosome can be highly effective in hydrolyses due to the physical proximity of hydrolysis and hydrolysis product removal. There may be cases where it is difficult for the cellulosome apparatus and cell to get physically close to the substrate, therefore individually secreted cellulases may be more effective (Beguin *et al.* 1998). *Caldicellulosiruptor sp.* has no such organelle and secretes their cellulolytic enzymes out into the medium, or they are bound to the cell's surface (Brunecky *et al.* 2013, Morrell-Falvey *et al.* 2015). The fact that *Caldicellulosiruptor sp.* are robust cellulolytic organisms with a distinct metabolism (Figure 1.3) and physiology from other cellulose degraders, such as *C. thermocellum,* increases the options when optimization of CBP is considered.

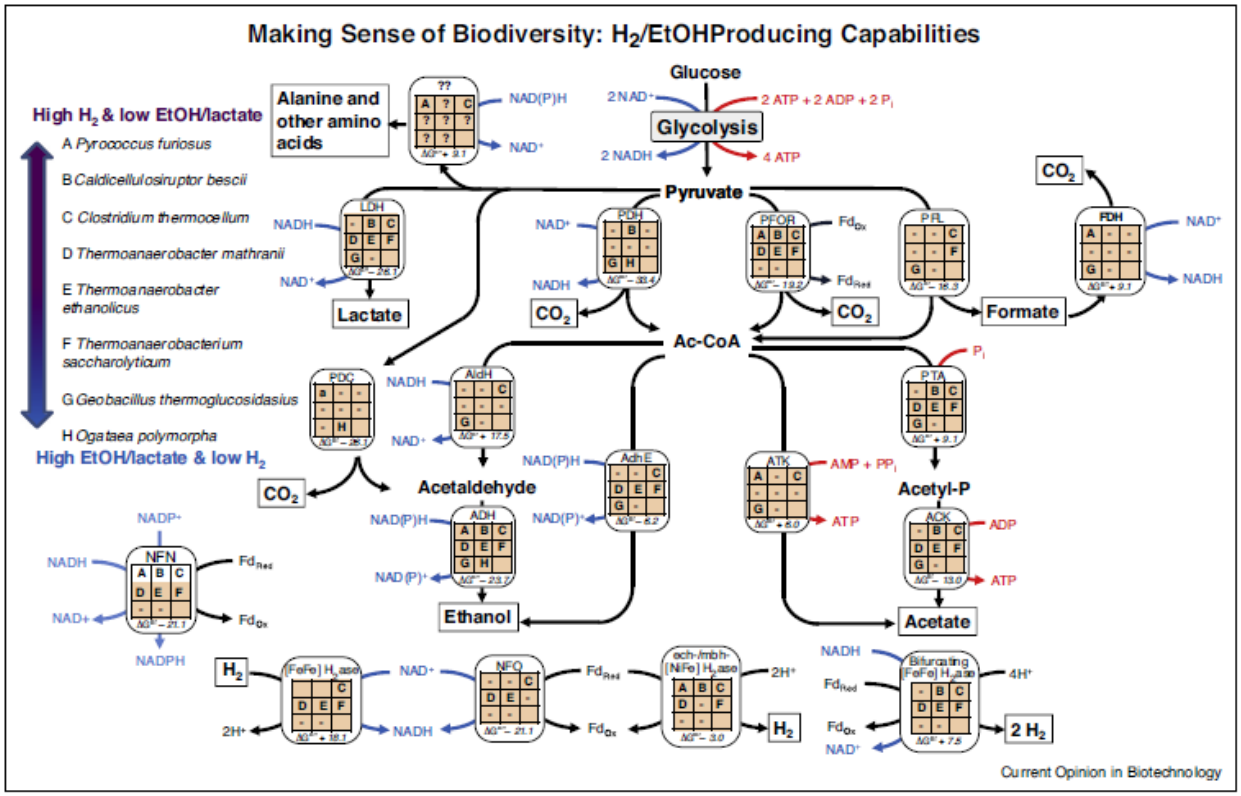
1.6.3. *C. phytofermentans* Role in Consolidated Bioprocessing

C. phytofermentans represents a mesophilic model for CBP compared to *C. thermocellum* and *C. caldicellulosiruptor* which are thermophilic (Warnick *et al.* 2002, Tolonen *et al.* 2009). Being thermophilic is generally considered a net positive over being mesophilic as high temperatures can be more favorable for H_2 production (Van Groenestijn *et al.* 2002), allow distillation of alcohols during production, and alleviate contamination issues (Lovitt *et al.* 1984). Sometimes being mesophilic can be beneficial as tolerance to high concentrations of alcohols may be more difficult at increased temperatures (Lovitt *et al.* 1984). *C. phytofermentans* allows pairing with well-studied mesophilic organisms such as yeast expanding the possibility and potential conditions for CBP to function when co-culturing is considered (Zuroff *et al.* 2013).

Warnick *et al.* (2002) show that lignocellulosic degradation is mainly due to one glycosyl hydrolase in *C. phytofermentans.* Petit *et al.* (2015) recently published a genome and transcriptome analysis on *C. phytofermentans* where their goal was to understand lignocellulosic biomass conversion into ethanol. They found *C. phytofermentans* was able to efficiently convert sugars into biomass, and that this was likely due to several factors: i) having an *adh* which creates ethanol from either NADPH or NADH, ii) effectively utilising pyrophosphate dependent enzymes to squeeze as much energy out of glycolysis as possible, iii) having the ability to easily get rid of reducing equivalents, and iv) creating more energy per sugar consumed due to the creation of a sodium gradient.

1.6.4. *C. cellulolyticum* Role in Consolidated Bioprocessing

C. cellulolyticum is a mesophilic strict anaerobe that is capable of producing hydrogen and ethanol from lignocellulosic substrates (Petitdemange *et al.* 1984). Typically, yields of ethanol are poor as a variety of end products compete for electrons and carbon. This has been remedied through genetic engineering and targeting of genes associated with the production of lactic acid (Li *et al.* 2012). Recently, Gaida *et al.* (2016) genetically engineered *C. cellulolyticum* to produce high yields of *n*-butanol by taking the *n*-butanol producing genes from *C. acetobutylicum* and putting them into *C.cellulolyticum*. While there is a focus on ethanol, thoroughly understanding organisms at a systems level should allow for genetic modification of organisms to produce a variety of desired end-products from CBP.



A, B, C, and G: from Carere CR, Rydzak T, Verbeke TJ, Cicek N, Levin DB, Sparling R: Linking genome content to biofuel production yields: a meta-analysis of major catabolic pathways among select H2 and ethanol-producing bacteria. *BMC Microbiol* 2012, **12**:295. **D** and **E** are from Verbeke TJ, Zhang X, Henrissat B, Spicer V, Rydzak T, Krokhin OV, Fristensky B, Levin DB, Sparling R: Genomic Evaluation of *Thermoanaerobacter* spp. for the Construction of Designer Co-cultures to Improve Lignocellulosic Biofuel Production. *PLOS ONE* 2013, **8**: e593625758. **F**: while based on Shaw *et al.* (2008), was complemented by manual search and BLAST to confirm that the NFOR is related to *nfnAB*, that the *hyd* is related to the bifurcating hydrogenases. A further Fe–Fe hydrogenase was observed in the genome. The absence of other genes was confirmed both from the annotation as well as BLAST anchored in *C. thermocellum* and *T. thermohydrosulfuricum* WC1, including lack of membrane bound RNF-type NFO. ***nfnAB***: Presence/absence was based on Wang S, Huang H, Moll J, Thauer RK: NADP+ reduction with reduced ferredoxin and NADP+ reduction with NADH are coupled via an electron bifurcating enzyme complex in Clostridium kluyveri. *J Bacteril* 2010, **192**: 5115–23. For *C. thermocellum* it was through the analysis by Rydzak T, Grigoryan M, Cunningham ZJ, Krokhin OV, Ezzati P, Cicek N, Levin DB, Wilkins JA, Sparling R: Insights into electron flux through manipulation of fermentation conditions and assessment of protein expression profiles in *Clostridium thermocellum*. Appl Microbiol Biotechnol 2014, **98**: 6497–6510. With respect to **B** and **F** it was through BLAST and side-by-side location of both genes needed for *nfnAB*. The annotated genes in F corresponding to *nfnAB* were TheetDRAFT_0838 and 0839. **Lower case (a) for PDC**: based on Ma K, Hutchins A, Sung SJS, Adams MWW: Pyruvate ferredoxin oxidoreductase from the hyperthermophilic archaeon, *Pyrococcus furiosus*, functions as a CoA-dependent pyruvate decarboxylase. *Proc Natl Acad Sci U S A* 1997, **94**: 9608–13. ***O. polymorpha***: based on Ravin NV, Eldarov Ma, Kadnikov VV, Beletsky AV, Schneider J, Mardanova ES, Smekalova EM, Zvereva MI, Dontsova Oa, Mardanov AV, *et al.*: Genome sequence and analysis of methylotrophic yeast Hansenula polymorpha DL1. *BMC Genomics* 2013, **14**:837. Amino acid synthesis indicates organisms where this phenotype has been observed. Question marks indicate that amino acid production has not been reported in these organisms.

Figure 1.3. Comparison of mixed acid fermentation of several hydrogen and ethanol producers relevant to CBP production of biofuels. (Source: Olson *et al.* 2015)

1.7. Designed Co-cultures for CBP

One attractive method for adding features and enhancing processes such as CBP from lignocellulosic substrates is adding co-culture partners alongside a strong cellulose degrader such as *C. thermocellum* (Lynd *et al.* 2005, Jouzani *et al.* 2015). There has been co-culture work using cellulolytic organisms with non-cellulolytic organisms (Hann *et al.* 2015, Jouzani *et al.* 2015). The combination of a cellulolytic organism with non-cellulose degrading species (sp.) in general has been shown to improve the rate of cellulose hydrolysis end-product yields (Odom & Wall 1983, Geng *et al.* 2010, Fang 2010). Pairing two cellulolytic organisms may provide the added benefit of their cellulases working synergistically (Irwin *et al.* 1993, Arun *et al.* 2014), and perhaps even create a high titre of cellulases depending on how expression is regulated (Zhang *et al.* 2005). Jouzani *et al.* (2015) outlines several promising co-culture arrangements and a few examples of the recent work on these co-cultures have been included in this thesis.

1.7.1. Co-cultures of *C. thermocellum* with *Thermoanaerobacter sp.* or *Thermoanaerobacterium sp.*

C. thermocellum co-cultures with various *Thermoanaerobacter sp.*, and the related genus *Thermoanerobacterium*, have been studied for over 20 years (Mori 1995), and continue to be studied as they offer many benefits over pure *C. thermocellum.* Benefits for CBP of a *C. thermocellum-Thermoanaerobacter sp.* co-culture include: i) vitamin cross-feeding which can have a positive effect on both

ethanol production and growth (He *et al.* 2011), ii) increased substrate usage range (Fang 2010), iii) assistance in hydrolysis of lignocellulolytic substrates (Verbeke *et al.* 2013), and iv) increased ethanol production efficiency and yield (Fang 2010). While co-cultures can be a benefit this is not always true; introduction of a high lactate producer could compete for sugars and may divert carbon and electrons away from biofuel related products, therefore it is essential to characterize the properties of prospective co-culture partners (Verbeke *et al.* 2011). The production of many of these unwanted mixed acid fermentation products can be offset with the use of genetic engineering. Shaw *et al.* (2008) removed the ability of *Thermoanaerobacterium saccharolyticum* to produce lactate and acetate through genetic engineering, and showed an improvement in ethanol total yield of ~40%. In the study by Argyros *et al.* (2011) they delete genes necessary for the production of lactate and acetate in *C. thermocellum* and use the genetically engineered *T. saccharolyticum* created by Shaw *et al.* 2008. This resulted in 92g/l of avicel cellulose consumed producing 32g/l of ethanol which is over double the amount produced when compared to non-genetically engineered co-culture under identical conditions and 75% of the theoretical maximum. This is a significant improvement over typical *Thermoanaerobacter* or *Thermoanaerobacterium sp.* containing co-cultures (Jiang *et al.* 2013).

1.7.2. *C. besci* and *T. maritma* Co-Cultures

Aberu *et al.* (2016) show co-cultures of *C. besci* and *T. maritima* are both excellent hydrogen producers. *C. besci* can be utilized in CBP process as it is highly cellulolytic (Chung *et al.* 2015). *C. besci* and *T. maritima* co-cultures act in synergy and produce superior amounts of total hydrogen on cellobiose and xylose compared to pure cultures of *C. besci*. Aberu *et al.* (2016) show that the co-culture was effective in fermenting a raw lignocellulose substrate as well as, but not necessarily better than, pure cultures. Finding a good co-culture partner to enhance CBP is partly trial and error, and partly understanding these organisms at a systems level. While this co-culture did not appear to greatly enhance the overall process, perhaps a change in conditions or different strains might.

1.7.3. Co-cultures under Aerobic Conditions

Brethauer *et al.* (2014) demonstrated a co-culture where *Trichoderma reesei* hydrolyse the lignocellulosic substrate aerobically and *Saccharomyces cerevisiae* and *Pichia stipites* then work to ferment the free sugars into ethanol. Zuroff *et al.* (2013) use *C. phytofermentans*, a strict anaerobe and a yeast in a co-culture, to show cellulose degradation and ethanol synthesis under microaerobic conditions demonstrating a new and interesting mode of CBP where conditions are simultaneously aerobic and ethanologenic. This is unlike Breathaur *et al.* (2014) where two macro-environments exist by developing a multilayered biofilm on the surface of an oxygen diffusible membrane reactor. In the layer adjacent to the

membrane, the aerobic cellulolytic *T. reesei* consumes the oxygen and provides cellulases for saccharification, while the yeast in a further layer ferments the simple sugars to ethanol. In theory aerobic ethanol production is possible as the enzymatic complement to produce ethanol is not air sensitive, making fermentative growth possible aerobically (Bulder *et al.* 1964). Elimination of the need to generate anaerobic conditions prior to CBP would remove a level of complexity making the process simpler and possibly cheaper.

1.8. Bioprospecting for Consolidated Bioprocessing

While there is a variety of organisms currently being studied in relation to CBP, it is important to keep expanding our list of organisms that could be used effectively either through finding new organisms, or revisiting known, but poorly characterized organisms with respect to CBP (Zuroff *et al.* 2012). Searching for new organisms has the added benefit of isolating and characterizing organisms that may be interesting for novel properties unrelated to biofuels as well. Additionally, while genetic engineering approach can and have been used to optimize existing strains relevant to CBP, such as for example *C. thermocellum or T. mathranii* (Rydzak *et al.* 2015, Yao *et al.* 2010), there may be properties in yet to be discovered organisms that would provide an even better starting point for genetic optimization. Many of the cellulolytic organisms used in CBP have strictly anaerobic requirements such as *C. thermocellum, Caldicellulosiruptor sp.,* and *C. phytofermentans*. It makes sense to create enrichment conditions for cultures that current CBP organisms are weak in, such as vitamin requirement (Mori 1995, Fang 2010) or oxygen tolerance. Some

weaknesses for an organism may be quite difficult to overcome with genetic engineering due to the complexity or innate characteristics that are directly at odds with a desired phenotype. New organism(s) may have distinct advantages over *C. thermocellum* in pure culture, such as higher ethanol production (Papanek *et al.* 2015), ease of manipulation in pure culture (Mori 1995), high ethanol tolerance (Brown *et al.* 2011), and wide substrate usage (Izquierdo *et al.* 2014). Additionally, understanding the enrichments greatly increase our knowledge of how to create a robust lignocellulolytic designer consortiums for CBP, and the possible interactions of these organisms in their natural environment (Abdel-Rahman *et al.* 2016).

Overall there has been some development in the ability to create mutants in biofuels organisms to both increase our understanding and to optimize them for biofuel production in CBP (Papanek *et al.* 2015). Understanding of biofuel production at systems level is incomplete, and there is great diversity in core metabolisms; see figure 1.3 (Olson *et al.* 2015). The possibility remains that there may be better suited organisms, hence interest in bioprospecting and understanding new organisms for CBP (Arora *et al.* 2015)

1.9. Oxygen Removal/Oxygen Tolerance

Many biofuel-producing cellulolytic bacteria, including *C. thermocellum*, lack aero-tolerance and have not been shown to tolerate greater than 2% O_2 in the atmosphere (Kato *et al.* 2004, Ng *et al.* 1977). While members of the genus *Clostridium* are typically described as strict anaerobes, some members, including *C.*

straminisolvens and *C. intestinalis* encode genes required for aerotolerance, and have been shown to grow in microaerobic environments (Kato *et al.* 2004, Lee *et al.* 1989, O'Brien & Morris 1971). Lack of oxygen tolerance observed in some *Clostridia* may be due to regulatory mechanisms rather than to not having the genetic potential to combat oxygen toxicity. Indeed, when *perR*, an oxygen responsive regulator, has been deleted in *C. acetobutylicum*, this genetic deletion was shown to lend aerotolerance (Hillmann *et al.* 2009).

Aerotolerance in CBP can be useful for two main reasons i) lack of complexity in design of system, if oxygen does not have to be kept out and ii) eliminates the need to make the media or substrate anaerobic in a continuous feeding CBP set up, nor maintain a constant anaerobic environment during cell growth. Previously, it has been reported that co-cultures containing a *Clostridium* species paired with facultative aerobes can lead to oxygen removal in a sealed vessel followed by fermentation in both designed and enriched cultures (Tran *et al.* 2010, Miyazaki *et al.* 2008). Tran *et al.* (2010) used a designed *Bacillus subtilis* and *Clostridium butylicum* culture to achieve oxygen removal, followed by acetone-butanol-ethanol production. Miyazaki *et al.* (2008) and Ronan *et al.* (2013) show enrichment cultures containing *Geobacillus/Caldibacillus* related organisms could cause oxygen removal followed by ethanogenesis on a cellulosic substrate. Co-cultures created by Zuroff *et al.* (2013) containing *Clostridium phytofermentans* and yeast achieve aerotolerance via respiratory protection under microaerobic conditions. Environments that are aerated, such as compost, can be highly cellulolytic (Mohee *et al.* 1998, Fathallh *et al.* 2012) but typically are not fermentative when aerobic (Dionisi *et al.* 2015). From the

examples listed above, we know that creating an aerotolerant highly cellulolytic fermentative culture through bio-prospecting is conceptually possible, either by finding a new suitable organism or finding the appropriate partner for a known strictly anaerobic cellulose degrader within the co-culture.

1.10. *Geobacillus* and *Caldibacillus* in CBP

Representatives of the genus *Geobacillus* have been found in highly cellulolytic enrichments (Ronan *et al.* 2013, Miyazaki *et al.* 2008). Miyazaki *et al.* (2008) characterize enrichments with a strain of *Geobacillus sp.* designated kpuB3 which is closely related to *Caldibacillus debilis* by 16S rRNA gene sequence similarity. *Geobacillus* and the former member of *Geobacillus, Caldibacillus,* which have more recently been split from that genus, are thermophilic facultative anaerobes or obligate aerobes that grow well at ~60ºC (Coorevits *et al.* 2012). Of the more recently created genera, is the single species genus *Caldibacillus.* It has been described as an obligate aerobe (Banat *et al.* 2004), and will become more important in the subsequent chapters of this thesis. *Geobacillus* can display typical mixed acid fermentation making lactate, acetate, formate, CO_2, and ethanol (Cripps *et al.* 2009). *Geobacillus* do not produce H_2, making them good potential candidates for ethanol production, as H_2 generation would directly compete for electrons. As *Geobacillus sp.* produce end-products that compete with ethanol production there has been interest in metabolically engineering them to produce ethanol at a higher efficiency (Cripps *et al.* 2009) on sugar substrates. Some *Geobacillus* also possess the innate characteristic of

high ethanol tolerance (Fong *et al.* 2006), which may be difficult to create through genetic modification. *Geobacillus* have been found growing along with *C. thermocellum* (Ronan *et al.* 2013, Miyazaki *et al.* 2008) in enrichments, therefore, a designer co-culture should be possible. A designer co-culture containing *C. thermocellum* and a *Geobacillus sp.* could be highly cellulolytic and may show benefits in ethanol production or culturing requirements over *C. thermocellum* in pure culture. Furthermore if the organism paired with *C. thermocellum* is facultatively anaerobic, then it could allow for respiratory protection analogous to *C. phytofermentase* and yeast by Zuroff *et al.* (2013). An aerotolerant designed co-culture has not yet been demonstrated for cultures involving *C. thermocellum*.

1.11. Omics for Microbial Characterization and Predictive Leverage

Current high throughput Omics techniques are widely used for the purposes of hypothesis building (Zoldoš *et al.* 2013). The employment of metagenomics can also be used to look for genes, organisms, and communities of interest (for example looking at microbial communities from ruminants, Dube *et al.* 2015). Martins *et al.* (2013) employed metagenomics to show that their lignocellulosic compost is being degraded by bacterial cellulases likely produced by organisms in the *Clostridiales* and *Actinomycetales*. Knowing the mode of degradation and the organisms involved in the degradation provides invaluable information for bioprospecting, as these organisms can now be targeted directly for isolation. Likewise, their cellulase genes can be cloned and expressed in other organisms. Instead of investigating natural

environments, another tactic is to create the desired environmental conditions, and then select for an adapted community. Yu *et al.* (2015) sought to analyse switchgrass degrading enrichment communities and the effect of preservation over time. The component members necessary for switchgrass degradation in the enrichment might be ideal for switchgrass degradation compared to other organisms that were not selected for on switchgrass

Omics including genomics, transcriptomics, and proteomics offer valuable information about an organism's inner workings (Mclean *et al.* 2013), and can be used for strain characterization related to biofuels (Verbeke *et al.* 2013). A well-annotated genome can provide insight into the potential end-product generated, substrate usage, auxotrophies, and presence of other biofuel related genes (Sczesnak *et al.* 2011, Verbeke *et al.* 2013). The transcriptome and proteome can give insight into the expression levels of biofuel related genes at the translational and protein level (Verbeke *et al.* 2014). As a systems level understanding of an organism is increased, such as ethanol production in *Thermoanaerobacter sp.* mentioned in section 1.5.1, this allows for further exploitation of *Thermoanaerobacter sp.* for alcohol production (Shaw *et al.* 2008, Olsen *et al.* 2015). This same approach can be applied to any other microorganism of interest.

Omics information is strengthened and verified by physiological measurements of the organism in question; in this way the annotation quality and predictive power of Omics increases over time (Munir *et al.* 2016, Rydzak *et al.* 2012). Carere *et al.* (2012) and Olsen *et al.* (2015) used genome analysis to predict organisms that may have good biofuel properties, essentially bioprospecting *in silico*.

This type of work will become more powerful and accurate as annotation quality improves and the number of genomes sequenced increase.

An example of this is Olson *et al.* 2015 (see figure 1.3); depending on the genome complement, one can hypothesize whether a 100% maximum theoretical ethanol yield is possible and/or likely based on the analysis of genome content. For instance, an organism that uses pyruvate formate lyase (PFL) for pyruvate fermentation will have difficulty creating the 100% maximum theoretical ethanol yield as electrons would be tied up in formate. One could choose an organism that expresses PFL, and enhance ethanol through the deletion of this gene through genetic modification (Rydzak *et al.* 2015). Through genome analysis as exemplified in figure 1.3, hypotheses can be generated about the abilities of organisms that have been sequenced. But looking at and understanding the gene complement of an organism is only the first step, we must also understand which genes are being translated and transcribed. Dai *et al.* (2015) analysed the metatranscriptome of the cow rumen to look for cellulases, allowing us to see which cellulase genes are actually being expressed at the transciptomic level. Knowing which genes are actually expressed is essential to build hypotheses and understand cellulose degradation in organisms at a systems level.

1.12. Conclusion

There can be both an environmental and economic benefit to biofuel production (Lynd *et al.* 2005). It makes sense to further develop CBP by first bioprospecting and characterising organisms that counter weakness in organisms typically used in CBP. Creating a robust set of organisms that can exploit a range of different operating modes for CBP will be a critical step in making CBP cost effective. At the same time, it is important to create tools for genetic modification and begin optimizing promising organisms. As these tools are developed they can then be applied to new organisms found through bioprospecting. Finding, optimising, and understanding organisms should be considered an iterative process, which should lead to incremental improvements in biofuel technology over time. Furthermore the pace at which it is iterated should improve with technological advances such as high throughput omics.

1.13. Thesis Objectives:

I set out to find new organism(s) suitable for CBP, or that would be able to act synergistically with those currently used. The goal was to identify and characterize organism(s) or co-culture partners that would excel at CBP and possess aerotolerant characteristics. The general workflow was as follows:

Chapter 2

Objective: Find and describe aerotolerant cellulolytic fermentative consortia.

This Objective was reached through the following tasks:

1) Bioprospect for organisms using conditions to enrich for: i) highly cellulolytic cultures; ii) robust cultures (transferable/ platable); and iii) functions that complement CBP (minimal media, aerotolerance).
2) Identify and purify organism(s) within these enrichments using: i) DGGE to identify genera and tentatively identify species and ii) tentative identifications to aid in colony isolation.
3) Characterize the physiology of enrichments and isolates, leading to the selection of a champion enrichment culture.

Chapter 3

Objective: Determine the minimum consortium with the aerotolerant phenotpye and characterize the enrichment, designer co-culture and *C. debilis* GB1.

This Objective was reached through the following tasks:

4) Recreate the most promising enrichment found in Chapter 2 from individual isolated strains and characterized organisms from pure culture.
5) Characterize the novel strain providing co-culture aerotolerance, *C. debilis* GB1, physiologically against its type strain Tf by comparing growth, end-products and substrate usage characteristics.

Chapter 4

Objective: Characterize enrichment isolate GB1 using genomics and proteomics.

This Objective was reached through the following tasks:

6) Characterize *C. debilis* GB1 under aerobic and anaerobic growth by: i) sequencing genome of constituent (*C. debilis* GB1) whose sp. has not been previously sequenced; ii) using comparative proteomics to understand regulation and expression of core metabolism, and iii) comparing and contrasting proteome information with physiological information from Chapters 2 and 3.

Chapter 5

Objective: To understand the observed physiological differences in GB1 and Tf at the genomic level.

This Objective was reached through the following tasks:

7) Characterize the type strain of *C. debilis* Tf against our isolate *C. debilis* GB1 at the genomic level by: i) using comparative genomics to understand differences between strains and ii) comparing and contrasting genome comparison information with physiological information from chapters 2 and 3.

1.14. Work not Included in the Thesis Chapters

I also spent time in NZ bioprospecting for cellulolytic enrichments, this work lead to isolation of *F. pennivorans* DYC, work on this bacterium was tangential to my thesis goals and is attached within the appendices (Appendix A).

Chapter 2: Characterization of Enriched Aero-tolerant Cellulose Degrading Communities for Biofuels Production Using Differing Selection Pressures and Inoculum Sources[1]

2.1. Abstract

Ethanol production from direct cellulose fermentation has mainly been described as a strictly anaerobic process. The use of air tolerant organisms or consortia for this process would reduce the need for pre-reduction of the medium and also permit continuous feed of aerobic feedstock. To this end, moderately thermophilic (60 ^{o}C) consortia of fermentative, cellulolytic bacteria were enriched from 3 distinct environments (manure, marsh, and rotten wood) from a farm in South-Eastern Saskatchewan, Canada. Community phenotypic and metabolic profiles were characterized. Selection methods, including direct plating under an aerobic atmosphere and repeated passaging, were designed to select for robust, stable aero-tolerant cellulose degrading communities. Several of the isolated communities exhibited an increase in total cellulose degradation (up to 2g/l cellulose) and total ethanol yield when compared to a monoculture of *C. thermocellum* DSMZ 1237 under batch conditions. Due to stringent selection conditions, low diversity enrichments were found, and many appeared to be binary cultures via denaturing gradient gel electrophoresis (DGGE) analysis. On the basis of 16S rRNA gene sequencing, aerobic conditions selected for a mix of organisms highly related to *C.*

thermocellum and *Geobacillus* species, while anaerobic conditions led to the development of consortia containing strains related to *C. thermocellum* with strains from either the genus *Geobacillus* or the genus *Thermoanaerobacter*. The presence of a *Geobacillus*-like species appeared to be a prerequisite for aero-tolerance of the cellulolytic enrichments, a highly desired phenotype in lignocellulosic CBP (consolidated bioprocessing).

2.2. Introduction

There is current interest expressed in cellulose containing biomass as a feed-stock for biofuel production (Demain *et al.* 2005, Islam *et al.* 2006). Environmental degradation of recalcitrant substrates such as lignocellulosic biomass is a complex process typically involving complex microbial communities (Wongwilaiwalin *et al.* 2010). These multi-species integrated communities may possess several benefits over pure cultures with respect to hydrolysis of lignocellulosic substrates. In fact, the combination of a cellulolytic organism with non-cellulose degrading species (sp.) has been shown to improve the rate of cellulose hydrolysis, end-product yields, and aerotolerance (Odom & Wall 1983, Geng *et al.* 2010, Fang 2010, Tran *et al.* 2010).

Clostridium thermocellum, a model organism for consolidated bioprocessing, has one of the highest rates of cellulose hydrolysis reported (Lynd *et al.* 2002) and is able to convert cellulosic biomass into several different products including H_2 and ethanol (Islam *et al.* 2009), but is a strict anaerobe. Growth analyses of cellulose degraders such as *C. thermocellum* have shown an excess of hydrolyzed sugars in

early exponential phase (Islam *et al.* 2009). When cellulolytic organisms are grown with other non-cellulolytic fermentative organisms, the excess sugars can be utilized by the non-cellulolytic organism, which can positively affect end-product yields (Fang 2010, Geng *et al.* 2010). It is expected that a co-culture of a cellulose degrader with specific partners could enhance end-product production in the co-culture and has the potential to speed up the rate of cellulose hydrolysis via product removal (Sharma 1991, Geng *et al.* 2010). For example, several studies have also shown enhanced lignocellulosic fermentation by co-culture of a *Thermoanaerobacter* sp. with *C. thermocellum* (Fang 2010).

Several attempts have been made to develop thermophilic lignocellulosic co-cultures with aero-tolerance. These communities can include a *Geobacillus* sp. that is either aerobic or facultatively anaerobic (Miyazaki *et al.* 2008). A facultatively anaerobic organism in culture with a strict anaerobe not only alleviates the need for pre-reduction of a medium, but could also serve as a pre-treatment for the substrate (Tran *et al.* 2010). Besides increasing end-product yields, providing aero-tolerance, and increasing cellulose degradation rates, there are several reports of cross-feeding essential vitamins and amino acids in microbial communities, which may further enhance the co-culture's growth capability (Mori 1995, Fang 2010). Previous work by Miyazaki *et al.* (2008) demonstrated the possibility of a strict anaerobe and facultative anaerobe creating a highly cellulolytic oxygen depleting thermophilic co-culture, an attempt to isolate a minimal functional community using aerotolerance, thermophilic conditions, and cellulose hydrolysis as selection pressures to achieve a discrete highly

cellulolytic aerotolerant thermophilic co-culture containing a strict anaerobe would represent novel work.

The current paper describes low diversity consortia capable of cellulolytic growth in the presence of an oxygen-containing atmosphere. The aim of this study was to select and characterize mixed cultures of cellulose degrading bacteria from environmental samples, and identify robust aero-tolerant cultures for future study.

2.3. Materials and Methods

2.3.1. Inocula and Enrichment Conditions

Samples including marsh soil, fresh cow feces, and rotted wood were collected from a farm site in South-Eastern Saskatchewan, Canada (Latitude, 50.359802; longitude, 101.919297; collected June 1, 2009). Samples, both liquid and solid, were collected aerobically, and stored in sealed containers without airspace at 4 ^{o}C. Sample liquid, or a slurry created using distilled-deionized water (diH_20) for solid samples (1 mL), was inoculated using conditions described in Table 2.1 (column 3).

2.3.2. Variation in Growth Medium and Selection Conditions

Sealed Balch tubes (26 mL) and 110 mL serum bottles supplied by Bellco Glass Inc. and Fisher Scientific, respectively, were used to carry out the experiments. Tubes containing10 mL of medium were prepared and adjusted to pH 7.2. Media preparation and protocols for anaerobic culturing were as described by Islam *et al.*

(2006). Unless otherwise specified, a modified 1191 medium, referred to as M-1191 medium (Islam *et al.* 2006), containing only 0.76 g/L yeast extract (YE), was used. Whatman paper #1 (2 g/L) was used as carbon and energy source, unless otherwise specified. Cellulose overlay plates were made by placing 55 mm Whatman paper disks on top of solidified M-1191 medium containing 15% agar. Czapek peptone medium (ATCC 522) was also prepared under aerobic conditions for conditions outlined in Table 2.1. Different selection pressures (Table 2.1, column 3) were used in an attempt to select for different co-cultures. After initial selection conditions were applied, samples were passaged 6 times anaerobically and 3 times aerobically (when possible) in sealed Balch tubes to obtain stable cultures. Tubes that tested positive for growth on cellulose were then plated anaerobically (and aerobically when possible) on Whatman paper overlays. Anaerobic conditions for plating were produced using a GasPak anaerobic container system. Cellulolytic colonies were then re-streaked 3 times and transferred back into anaerobic broth cultures. Pure cultures were obtained through plating and re-streaking on cellobiose plates.

2.3.3. Experimental Setup

All cultures were inoculated at 10% v/v from exponentially growing source cultures. Strong positive cellulolytic activity was revealed with the disappearance of 2g/L Whatman paper after 48 hours. All experiments were carried out with three independent replicates (i.e. in triplicate). Samples (1 mL) were taken for end-product

analyses at 24 hours (h) post-inoculation (pi) from cellobiose cultures and at 48 h from cellulose cultures and stored at -20 ^{o}C until analysed.

2.3.4. Sugar and End-Product Analyses

Cellobiose, glucose, lactate, formate, acetate, and ethanol were measured by high pressure liquid chromatography (HPLC) using a Dionex, ICS 3000 system equipped with a Bio-Rad Aminex-87H column, and run at 30 ^{o}C, 0.75mL/min, with 0.02 mM sulfuric acid. A Shodex 101 Refractive Index detector was used on all compounds being analysed. Measurements for CO_2, H_2, O_2, were taken on a Multiple Gas Analyzer #1 Gas Chromatograph (GC) System Model 8610-0070 (SRI Instruments, Torrance, CA) with a Thermal Conductivity Detector (TCD), and using argon as the carrier gas. Columns and methods were used as previously described by Rydzak *et al.* (2009).

2.3.5. DNA extraction and PCR Amplification

DNA extractions from cultures were performed using a Promega Wizard Genomic Extraction Kit. PCR of the genomic DNA with 16S rRNA gene primers 341F (5'-CCTACGGGA GGCAGCAGCGCCCGGGGCGCGCCCCGGGCGGGGCGGGGGCACGGGGGG-3') and 907R (5'-CCGTCAATTCMTTTGAGTT T-3'; (Sanchez *et al.* 2007). Pure cultures, when isolated from single colonies, were identified by amplification and sequencing of the 1533 bp fragment of the 16S rRNA gene using the 8F (5'-AGAGTTTGATCCTGGCTCAG-3') and 1541R (5'-AAGGAGGTGATCCAGCCGCA-3') primers (Verbeke *et al.* 2011).

2.3.6. Denaturing Gradient Gel Electrophoresis (DGGE)

A Denaturing Gradient Gel Electrophoresis (DGGE) protocol, as described by Muyzer *et al.* (1993), was used with some modifications. PCR products were separated on the Bio-Rad D-Code system with 40%-70% denaturing gradient polyacrylamide gel for 18 h at 60 ^{o}C, 80 Volts (V). Bands were then excised, soaked in 50 µL ddH_2O for 4 h, and centrifuged for 1 min at 19400g. The supernatant was then used as template for amplification and sequencing to identify bacteria.

2.3.7. DNA Sequencing and Phylogenetic Analyses

Sequencing of re-amplified DNA from excised DGGE bands was completed through Macrogen (Rockville, USA). Sequences were trimmed manually, and aligned for a consensus sequence using Bio-Edit. Sequences were run through NCBI BLAST (http://blast.ncbi.nlm.nih. gov/Blast.cgi) to determine possible matches and identify tentative species based on sequence identity to the known 16S rRNA sequence database. (KC291677-KC291704)

2.4. Results and Discussion

2.4.1. Culture Enrichment

Environmental samples were inoculated into Balch tubes or directly onto plates under conditions described in Table 2.1. Stable enrichments were stored at -80 ^{o}C for long-term storage and at 4 ^{o}C for working stocks. These served as sources of inocula for additional experiments including DGGE analysis and anaerobic end-product data.

2.4.2. Analysis of Microbial Community

Based on DGGE, followed by band excision and sequencing, a tentative identification of the strains present in each enrichment was made, DGGE gel is shown in figure 2.1. Table 2.2 lists the different enriched cultures with the tentative identifications of bacteria via 16S rRNA gene sequence analyses. Table 2.3 lists end-products produced by enrichments under anaerobic conditions in M-1191 media with cellulose as the substrate. All stable enrichments contained a strain related to *C. thermocellum* (97-100% nucleotide sequence identity), suggesting that a *C. thermocellum*-related organism may be the key member in cellulose degrading communities under these conditions (Kato *et al.* 2004, Shiratori *et al.* 2009). All of the cultures that could degrade cellulose on aerobic overlay plates contained members highly related to *Geobacillus* sp., suggesting that the metabolism of these organisms created a sufficient oxygen gradient on the cellulose to allow the growth of the anaerobic cellulolytic member (*C. thermocellum* in this case).

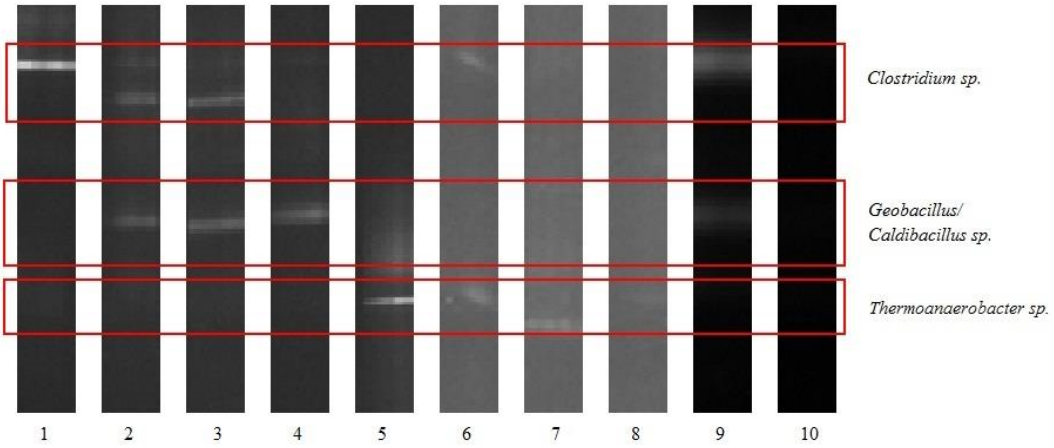

Figure 2.1. Denaturing gradient gel electrophoresis gel bands of isolated co-cultures. Red boxes represent areas of excision where amplification and viable sequences were obtained. Gels: 1, Clostridium thermocellum; 2, CNR1; 3, BN; 4, B4-1; 5, CN; 6, N2; 7, CP; 8, WS; 9, N4; and 10, N4P. For description of samples, please see Table 2.1.

Table 2.1. Samples and selection conditions

Sample	Culture Name	Strategies Employed [a]
Marsh	B4-1	Repeated anaerobic subculture
Marsh	BN	Low nutrient defined medium (1191 aerobic no YE)
Marsh	CP	Aerobic modified czapek peptone media
Marsh	N4	Aerobic plating/ anaerobic incubation
Marsh	N4P	Repeated aerobic sub culturing + aerobic plating
Marsh	N2	Direct anaerobic plating
Cow Feces	CNR1	Repeated anaerobic sub culturing
Cow feces	CN	Anaerobic plating
Wood Slurry	WS	Repeated anaerobic sub culturing

[a]Standard medium is M-1191 with cellulose unless indicated otherwise.

Table 2.2. List of cellulolytic consortium and organisms within identified by DGGE 16s rRNA fragment analysis

	Principal organisms present based on DGGE analysis			
Culture name[a]	No.	Commonly cellulolytic [b]	Not commonly cellulolytic[b]	Aerotolerance test[f]
Aerobic selection pressures				
BN	2	*C. thermocellum*[c]	*Caldibacillus debilis*	+
CP	3	*C. thermocellum*[d]	*Clostridium caenicola* , *Thermoanaerobacterium sp.*	-
N4	4	*C. thermocellum*	*Caldibacillus debilis* , *Geobacillus thermoglucosidasius*,*Geobacillus Y4.1MC1*	+
N4P	4	*C. thermocellum, Clostridium stercorarium*[e]	*Caldibacillus debilis* , *G. thermoglucosidasius*	+

WS	3	*C. thermocellum*	*Caldibacillus debilis, G. thermoglucosidasius*	+

[a]Please see Table 2.1 for details regarding cultures.

[b]Closest species identified in the NCBI database by BLAST analysis, based on a 97% or greater 16S rRNA nucleotide sequence identity. Due to the short 16S rRNA sequence length used, BLAST analyses of some fragments resulted in ambiguous species identification.

[c]BLAST analysis of this 16S rRNA sequence also resulted in 97% or greater sequence identity to *Clostridium clariflavum*.

[d]BLAST analysis of this 16S rRNA sequence also resulted in 97% or greater sequence identity with *Clostridium spp.* strain TG60-1, *Clostridium thermosuccinogenes*.

[e]BLAST analysis of this 16S rRNA sequence resulted in less than 97% sequence identity with this species.

[f]The test for aerotolerance consists of plating a stable coculture aerobically on cellulose overlay plates. A positive (+) result constitutes presence of at least one colony-forming unit.

Table 2.3. End products from anaerobic batch cultures for comparison against *Clostridium thermocellum* DSMZ 1237 in monoculture

Microorganisim/Consortia Name (Anaerobic)	End-products expressed in mol/mol glucose equivalent consumed (total yield in mmol)						Total glucose equivalents consumed (mmol)
	Formate	Acetate	Ethanol	Lactate	CO_2	H_2

CN	0	0.3	0.3 (3.1)	1.4	0.7	0.6 (6.2)	10.3

Note: All measurements were conducted in triplicate with variations less than 15%. All cocultures were grown on cellulose excess except for the noncellulolytic *Geobacillus spp.* monocultures, which used cellobiose

Anaerobic plating did not result in the isolation of any cellulolytic strains in pure culture. This could be due to a dependence of the wild strains related to *C. thermocellum* on one or more companion species in the enrichments isolated, under the conditions used in this work. Cellulolytic colonies on cellulose overlay plates appear to contain a minimum of 2 species via DGGE analysis (N4, N4P, CP, N2), and none of the identified pure colonies on cellobiose plates matched either the *C. thermocellum* phenotype, or contained 16S rRNA gene sequences matching *C. thermocellum*. Instead, the 16S rRNA gene sequence for individual colonies matched *Geobacillus*, *Caldibacillus*, *Thermoanaerobacterium*, and *Thermoanaerobacter spp*.. The 16S rRNA sequence analyses did, however, identify species in the co-cultures that matched *Geobacillus* species, and aerobic plating on cellobiose resulted in the isolation of a pure strain of 2 *Geobacillus* species. 16S rRNA gene sequence analyses of the two pure isolates of *Geobacillus* revealed 99% nucleotide sequence identities with *G. debilis* strain tf (Banat *et al.* 2004), now called *Caldibacillus debilis* (Coorevits *et al.* 2012) and *G. thermoglucosidasius* NCIMB 11955 (Cripps *et al.* 2009*).*

The ability of the *C. thermocellum*-*Caldibacillus debilis* enrichment to carry out cellulose degradation under aerobic conditions suggests that it might be the minimal functional community for aero-tolerant cellulose. Many *Geobacillus* species have been shown to produce biofuels from starch or glucose, and have been genetically modified to produce high amounts of ethanol (Cripps *et al*. 2009). A subset of *Geobacillus* species possess properties the may be useful for biofuel production, are facultatively anaerobic (Banat *et al.* 2004), possess glycosyl

hydrolases (Shalom *et al.* 2002), possess sugar metabolisms that complement lignocellulosic fermentations (Banat *et al.* 2004), display low lactate production (Martin *et al.* 1992), and are highly tolerant of ethanol (Fong *et al.* 2006). Many examples of *Geobacillus* species with some of these features are described in the literature, although none have been tested for all of these features at the same time.

Members of the genus *Thermoanaerobacter*, strictly anaerobic thermophilic Firmicutes, have also been explored for their biofuel potential, and several studies have shown that co-cultures containing *C. thermocellum* and *Thermoanaerobacter ethanolicus* 39E display several advantages over a monocultures of *C. thermocellum* for the production of biofuels from lignocellulosic substrates (Fang 2010). Studies have also suggested vitamin cross-feeding between a *Thermoanaerobacter* sp. and *C. thermocellum,* showing a mutualistic relationship between them (Mori 1995). Other environmentally isolated co-cultures may also have mutualistic relationships (Mori 1990). Strictly anaerobic thermophilic members of the genus *Clostridium* within the consortia such as *C. stercorarium, C. clariflavum,* and *C. caenicola* have also been isolated in cellulosic enrichments (Izquierdo *et al*. 2010, Shiratori *et al.* 2009).

Different end-product synthesis patterns were displayed by enrichments under anaerobic conditions (Table 2.3). Some enrichments produced formate, lactate, ethanol, acetate, H_2, CO_2, all of which are synthesized by known strains of *C. thermocellum* (Rydzak *et al*. 2009). The highest ethanol concentrations produced by the enrichments were observed with the enrichments that appeared to be binary-cultures BN, N2, N4, and N4P in which a bacterium highly similar to *C. debilis* was the complementary member of the community. Enrichments observed to produce high

lactate concentrations contained bacteria similar to *G. thermoglucosidasius* and *Thermoanaerobacter sp.*, both of which are known lactate producers (Cook 2000, O-thong *et al.* 2008, Cripps *et al.* 2009). From the perspective of the total production of ethanol, the *C. thermocellum*-*Caldibacillus debilis* containing enrichments out-performed *C. thermocellum* mono-cultures (Table 2.2), possibly due to increased substrate conversion (see Table 2.3), *C. thermocellum* had a higher specific yield of ethanol, displaying higher yields of ethanol/mol glucose equivalent consumed. With respect to H_2, *C. thermocellum* mono-cultures outperformed enrichments in both total production as well as specific yields.

In our work, only two species appeared to be able to complement the *C. thermocellum*-like species in enrichments under conditions used, one related to a *Geobacillus* sp. under aerobic conditions and one related to *Thermoanaerobacter* sp. under anaerobic conditions. Most of the samples had direct interaction with the soil, from which *Geobacillus* species have been isolated. Samples derived from cow feces did not yield aero-tolerant enrichments (Marchant *et al.* 2002), and did not give rise to a *Geobacillus* sp. within their co-cultures. Enrichment CP, which appears to be composed of strict anaerobes, was passaged aerobically and presumably these anaerobes were able to overcome the oxygen due to the low solubility of atmosphere at 60ºC in media, however when tested for the ability to plate out aerobically on cellulose overlay plates no Colony forming units were observed.

An argument for a mutualistic relationship between the organisms related to *Caldibacillus debilis* and *C. thermocellum* under aerobic growth can also be made. The *C. debilis* is dependent upon *C. thermocellum* to hydrolyze cellulose to

fermentable sugars, while *C. thermocellum* is dependent upon *C. debilis* to consume oxygen and create an anaerobic microenvironment (Tran *et al.* 2010). A likely scenario for the aero-tolerant cellulolytic communities isolated is the formation of a biofilm whereby an oxygen gradient is formed to allow conditions ideal for a *C. thermocellum*-like organism's growth. Similar cooperation has been described for methanogens (Kato *et al.* 1993). Previous work by Islam *et al.* (2006) under similar conditions report cellulose above ~1.1g/l (~6.1mmol glucose equivalent) was not degraded, enrichment total glucose equivalents consumed (Table 2.3) show roughly a doubling in total cellulose degradation and consumption, demonstrating potential benefits of enrichments over monoculture work using C. *thermocellum.*

2.5. Conclusion

The results of this study show the potential for enrichments containing a *C. thermocellum*-like species and *Geobacillus*-like species to simplify consolidated bioprocessing by removing the requirement for pre-reducing the medium or substrate. Several of the enrichments exhibited a higher total cellulose conversion, and increased total ethanol yield. Future studies will concentrate on degradation rate and efficiency of production optimization within these systems. Isolation of what appears to be the minimal functional community containing *C. thermocellum* which achieves aerotolerant cellulolytic thermophilic growth to produce biofuels represents the first step in creating an aerotolerant lignocellulosic designer co-culture for CBP. Further studies need to be completed to determine whether this aero-tolerant phenotype is

specific to B4-1 and similar enrichments or a general theme that may be possible with other *Geobacillus* sp. paired with other strict anaerobes.

Chapter 3: Characterization of the Facultative Anaerobe *Caldibacillus debilis* GB1 and its use in a Designed Aerotolerant, Cellulose Degrading, Co-Culture with *Clostridium thermocellum*[2]

3.1. Abstract

Development of a designer co-culture that can achieve aerotolerant ethanogenic biofuel production from cellulose can reduce the costs of maintaining anaerobic conditions during industrial consolidated bioprocessing (CBP). To this end, a strain of *Caldibacillus debilis* isolated from an air-tolerant cellulolytic consortium, which included a *Clostridium thermocellum* strain, was characterized and compared with the *C. debilis* type strain. Characterization of the isolate *C. debilis* GB1 and comparisons with the type strain *C. debilis* revealed significant physiological differences including: i) the absence of anaerobic metabolism in the type strain and ii) different end-product synthesis profiles under the experimental conditions used. The designer co-cultures displayed unique responses to oxidative conditions, including an increase in lactate production. We show here that when the two species were cultured together, the non-cellulolytic facultative anaerobe *C. debilis* GB1 provided respiratory protection for *C. thermocellum*, allowing for synergistic utilization of cellulose even under an aerobic atmosphere.

3.2. Introduction

Isolation and characterization of organisms with the ability to degrade and ferment cellulose is an essential step towards enhancing biofuel production via consolidated bioprocessing (Levin *et al* 2009). Designing a culture that could achieve both cellulose degradation and ethanol production under non-reduced conditions would reduce the costs and complexity of culturing strictly anaerobic bacteria, as this would eliminate the need for maintaining a reduced environment. *Clostridium thermocellum* is perhaps the best-studied model organism capable of consolidated bioprocessing (CBP) under anaerobic conditions (Lynd *et al.* 2005, Biswas *et al.* 2014). Co-culturing a cellulolytic organism with a non-cellulolytic partner capable of producing desired end-products at high rates and yields has been shown to improve overall biofuel production capability via CBP (Geng *et al.* 2010) and increased cellulose hydrolysis rates (Geng *et al.* 2010, Sharma 1991). Many biofuel-producing cellulolytic bacteria, including *C. thermocellum*, lack aero-tolerance and have not been shown to tolerate greater than 2% O_2 in the atmosphere (Kato *et al.* 2004, Ng *et al.* 1977). While members of the genus *Clostridium* are typically described as strict anaerobes, some members, including *C. straminisolvens*, *C. acetobutylicum*, and *C. intestinalis* encode genes required for aerotolerance, and have been shown to grow in microaerobic environments (Kato *et al.* 2004, Lee *et al.* 1989, O'Brien & Morris 1971). Moreover, genetic modification of *C. acetobutylicum* resulted in a significant increase in aerotolerance such that the recombinant strain was able to grow in the presence of atmospheric concentrations of oxygen (Hillmann *et al.* 2009).

Previously, it has been reported that co-cultures containing a *Clostridium* species paired with facultative aerobes can lead to oxygen removal in a sealed vessel followed by fermentation (Miyazaki *et al.* 2008, Ronan *et al.* 2013, Tran *et al.* 2010) or achieve aerotolerance via respiratory protection under microaerobic conditions (Zuroff *et al.* 2013). The importance of biofilms and the use of mixed cultures to help lignocellulosic degradation has also been highlighted recently (Zuroff & Curtis 2012). Ronan *et al.* (2013) highlighted the potential of stable, apparently aerotolerant, cellulolytic communities in fermenting cellulose to ethanol. Wushke *et al.* (Chapter 2) also described a stable enrichment culture, B4-1, capable of cellulolytic growth and fermentation in the presence of oxygen, that included *Caldibacillus debilis*-like and *C. thermocellum*-like bacteria. The *C. debilis* strain was subsequently isolated and named GB1.

The present paper aims to: i) characterize the *C. debilis* GB1 against the type strain, *C. debilis* Tf^{t} DSM 16016 and ii) demonstrate that the aerotolerant phenotype observed in the enrichment culture B4-1 can be achieved using a co-culture of *C. debilis* GB1 and *C. thermocellum* DSM 1237. To this end, we compared aerobic and anaerobic growth and end-product formation of *C. debilis* GB1, isolated from the cellulolytic aerotolerant ethanol-producing enrichment B4-1, against the type strain *C. debilis* Tf^{t} DSM 16016 isolated by Banat *et al.* (2004). Furthermore, the enrichment culture B4-1, primarily comprised of a *C. thermocellum*-like strain and *C. debilis* GB1, was compared against a co-culture containing *C. thermocellum* DSM 1237 and *C. debilis* GB1 under both aerobic and anaerobic conditions.

3.3. Materials and Methods

3.3.1. Culturing Method

Cultures of *C. thermocellum* DSM 1237 and *C. debilis* Tf^t DSM 16016 (hereafter referred to as *C. thermocellum* 1237 and *C. debilis* 16016, respectively) were obtained from the DSM culture collection. Enrichment culture B4-1 and *C. debilis* GB1, isolated from B4-1, were derived from previous work (Chapter 2). Modified 1191 medium (Islam *et al. 2006*), with a lower concentration of yeast extract (0.76 g/l) and pH adjusted to 7.2, was used for all experiments. Various sugars were used as carbon and energy source (at 2 g/L), including xylose, glucose, ribose, sucrose, arabinose, rhamnose, mannose, maltose, cellobiose, sorbitol, xylan, trehalose, as specified in the methods used for different experiments (see below).

Sealed Balch tubes (26 ml) and 110 ml serum bottles supplied from Bellco Glass Inc. (Vineland, NJ) and Fisher Scientific (Toronto, ON) respectively, were used to carry out experiments. Balch tubes were used for all substrate utilization experiments (Table 3.1) to compare *C. debilis* GB1 against *C. debilis* 16016. Anaerobic Balch tubes and serum bottles were prepared using the methodology described by Islam *et al.* (2006), while aerobic tubes and serum bottles were prepared using atmosphere in the headspace with no addition of the reductant sodium sulfide. Experiments designed to compare aerobic and anaerobic conditions (Table 3.1) utilized serum bottles with 10 ml media and 100 ml headspace.

3.3.2. Cell Growth

Prior to each experiment, cells were passaged once under the relevant condition to allow adaption to substrate and/or, in the case of co-cultures, to allow adaption to growth together. All experiments were carried out in triplicate using a 10% inoculum. All cultures were grown at 60ºC unless otherwise stated. Cultures grown for end-product sampling were grown with sampling points at 48 hours post-inoculation (h pi) (Table 3.1) in sealed aerobic Balch tubes contained 10 ml of media and 17 ml headspace. For Table 3.3 and Table 3.4, cultures were grown in serum bottles using 10 ml medium with 100 ml headspace to ensure oxygen excess throughout growth. Shaking (75 rpm) was used to equilibrate the medium with the gas phase. Sampling for end-products was taken at 72 h pi and 168 h pi. All cultures in Table 3.3 were grown under carbon excess conditions (5 g/L) with either cellulose or cellobiose. All cultures grown aerobically on cellulose were transferred with a cut-off pipet tip, as an intact biofilm appeared to enhance inoculation efficiency. Aerobiosis was also visually assessed during cell growth under relevant conditions via the pink colour of resazurin dye in the medium.

3.3.3. Physiological Characterization

Optical density OD_{600} was used to monitor cell growth in liquid media with soluble substrates. When the cells were grown on cellulose, substrate degradation, pH, end-product synthesis data, and protein concentrations were used to verify growth.

Protein concentrations were estimated by Bradford Assay (Bradford 1976), using a NanoDrop 1000 spectrometer.

3.3.4. Sugar and End-Product Analysis

Culture samples (1 ml) were collected after 48 hpi and stored at -20 ºC until analysed. Concentrations of cellobiose, glucose, ribose, trehalose, sorbitol, rhamnose, arabinose, maltose, mannose, sucrose lactate, formate, acetate, ethanol were measured by high pressure liquid chromatography (HPLC) using a Dionex ICS 3000 system equipped with a Bio-Rad Aminex-87H column, and run at 30 ºC, 0.75 ml/min, with 0.02 mM sulfuric acid. A Shodex 101 Refractive Index detector was used on all compounds being analysed.

Measurements of CO_2, H_2, and O_2 concentrations were determined using a Multiple Gas Analyzer #1 Gas Chromatograph (GC) System Model 8610-0070 (SRI Instruments, Torrance, CA), equipped with a Thermal Conductivity Detector (TCD), and using argon as the carrier gas. Columns and methods were used as previously described by Rydzak *et al*. (2009).

Welch's t-test was used to determine if ethanol production was significantly changed ($p<0.05$) in table 3.3 (Ruxton 2006). Glucose equivalents consumed were estimated from end-products produced using the formula: glucose equivalents = (C1/6) + (C2/3) + (C3/2). C1= formate and CO_2, C2= acetate and ethanol, and C3= lactate (Ellis *et al.* 2012).

3.3.5. Bioinformatic Analyses

The *C. thermocellum* DSM 1237 (NC_009012) and *C. debilis* 16016 (NZ_ARVR01000000) genomes were viewed and genes searched using IMG/er (Markowitz *et al.* 2008).

3.3.6. Culture Purity Confirmation

Monoculture purity was determined via 16S rRNA gene PCR amplification and sequencing using primers 8F (5'-AGAGTTTGATCCTGGCTCAG-3') and 1541R (5'-AAGGAGGTGATCCAGCCGCA-3'), and consistency of end-product production phenotype from literature and previous experiments (Chapter 2, Rydzak *et al.* 2009). The purity of the co-cultures (i.e. that they contained only *C. thermocellum* DSM 1237 and *C. debilis* 16016) was confirmed by PCR using the 16S rRNA interspacer primers, ITS-F 5'-GTCGTAACAAGGT AGCCGTA-3' and ITS-Reub 5'-GCCAAGGCATCCACC-3'. The resulting amplicons were compared against the interspacer profiles of the pure cultures using agarose gel electrophoresis (Cardinale *et al.* 2004).

3.4. Results

3.4.1. *Caldibacillus* Strain Comparison

C. debilis GB1 was deposited at the DSMZ and designated DSM 29516. Comparison of the *C. debilis* 16016 and *C. debilis* GB1 16S rRNA and *cpn60* gene sequences (16016 locus tags A3EQDRAFT_10000, A3EQDRAFT_00206; and GB1 GenBank accession numbers KF652080, KP259875) reveal high sequence identities (99.9%) for both. Growth of both strains on cellobiose at 60 °C revealed that strain GB1 grew similarly to 16016, both strains reaching similar cell densities as determined by OD_{600} (0.13), and total protein (Table 3.1). Growth of both strains on cellobiose was also measured and found to be similar at different temperatures (50, 55, 60, 65, and 70 ºC) as seen in Table 3.2. The growth rates for strain GB1 and 16016 were found to be optimal between 55 and 60 ºC (Table 3.2). Due to the low OD_{600} and high amount of cell lysis after reaching stationary typical of *C. debilis*, total protein/ml was used as an additional indicator of growth (Table 3.1).

Table 3.1. Substrate comparison of *C. debilis* strain 16016 and GB1 grown under static conditions in sealed Balch tubes on M-1191 at 48h post innoculation

Substrate	16016						GB1					
	Growth		End-Products (mM)				Growth		End-Products (mM)			
	Final pH[1]	µg protein/ml[2]	Lac[3]	Ac[3]	Form[3]	EtOH[3]	Final pH[1]	µg protein/ml[2]	Lac[3]	Ac[3]	Form[3]	EtOH[3]
Aerobic[4,5]												
cellobiose	5.5	118	0.6	14.4	6.3	-	5.5	106	-[4]	8.9	9.6	9.0
xylose	5.4	165	0.8	14.7	4.7	-	5.8	72	0.1	7.2	8.4	-
Anaerobic												
cellobiose	7.2	-	-	-	-	-	5.4	143	-	3.7	9.3	6.6
xylose	6.7	-	-	-	-	-	5.3	125	-	3.9	8.2	5.4

Tubes were incubated for 48h, for aerobic conditions. O_2 was measured by GC to ensure excess even at the end of the experiment. Also, the medium stayed pink indicating that the resazurin redox indicating dye was oxidized throughout the experiment.

[1]Standard deviation =<±0.1; [2]Standard deviation =<±6 µg; [3]Standard deviation =<±15%; [4]End-products of the media control were subtracted a dash (-) represents concentrations = or < Yeast extract controls. 16016 produced 0.1 mM lactate, 1.5 mM acetate and 0.9 mM formate and GB1 produced 0.1 mM lactate, 1.5 mM acetate, 0.5 mM formate; [5]Strain 16016 and GB1 also grew on xylose, ribose, glucose, mannose, cellobiose, sucrose, maltose tehalose under aerobic conditions

Table 3.2. Doubling Time of C. debilis GB1 and 16016 Between 50 and 70 ºC

Temperature (ºC)	GB1	16016
	Doubling Time (h)[1]	
50	6.25	6.00
55	1.78	2.18
60	1.71	3.00
65	3.29	2.96
70	5.33	3.00

[1]Standard deviation <=3%

A comparison of sugar utilization and end-product synthesis by strains GB1 and 16016 under aerobic and anaerobic conditions is summarized in Table 3.1. An increase in total protein concentrations, decrease in pH, and increase in end-product synthesis (when compared to the no substrate control) reveals that both strains 16016 and GB1 can grow aerobically on cellobiose, xylose, glucose, ribose, sucrose, mannose, maltose and trehalose, but not on sorbitol, arabinose, rhamnose or xylan.

The *Caldibacillus* genus, as presently described, indicates that they are obligate aerobes (Coorevits *et al.* 2012). While *C. debilis* 16016 was indeed confirmed to be a strict aerobe under the conditions tested, the novel isolate, strain GB1, was capable of both aerobic and anaerobic growth on the carbon sources tested: xylose and cellobiose (Table 3.1). Different end-product synthesis patterns were observed under aerobic and anaerobic growth for strain GB1. During anaerobic growth conditions (Table 3.1), *C. debilis* GB1 produced a higher acetate concentration while ethanol and formate formation remained at comparable levels (with the exception of xylose and ribose with which the GB1 cells did not produce any ethanol). Note that H_2 and CO_2 were not measured for experiments performed in Table 3.1.

A comparison of GB1 growth under anaerobic versus aerobic conditions, with shaking (Table 3.3), revealed that formate as an end-product was completely eliminated, and only acetate and CO_2 production was observed under aerobic conditions.

Table 3.3. End-Products (mmol/L of cell culture) After 72 and 168 Hours of Incubation at 60 ºC on M-1191 (shaken at 75 rpm)[1]

Microorganism/Consortia name	End products (mmol/L of cell culture)						O_2 consumed[4,7] (mmol/l of cell culture)	O_2 %[7]	Redox Balance
	Lactate[6]	Acetate[6]	Formate[6]	Ethanol[6, 8]	CO_2[6]	H_2[6]

[1] End-products produced from yeast extract control were subtracted from each condition (GB1 aerobically: CO_2=0.8 mmol/L of cell culture and O_2= 15 mmol/L of cell culture, GB1 anaerobically: 0.1 mM lactate, 1.5mM acetate and 0.4 mM formate), *C. thermocellum* did not produce any appreciable end-products from the media control; [2]All cultures were grown with cellulose excess (5g/L), with the exception of the pure culture of *C. debilis* GB1 where cellobiose (5 g/L) was used; [3] BD=below quantification limit (0.1 mM/L of cell culture); [4] t_0 has 100.7 mmol/L of cell culture of O_2 available; [5] only 72h shown for anaerobic samples as no change was observed at 168 hours, for aerobic contions measurements at 72h/168h is given; [6] standard deviation <= ± 10% for monocultures and =<±20% for co-cultures; [7] standard deviation <= ± 25%;

[8]Welch's t-test found a statically significant ($p<=0.05$) difference in ethanol production between *C. thermocellum* alone and *C. thermocellum* in co-culture under anaerobic conditions (20).

3.5. *Caldibacillus debilis* Plus *Clostridium thermocellum* Co-Culture

A picture of the designer co-culture grown aerobically on cellulose overlay plates can be found in Appendix B within the appendices.

Interspacer analysis (Cardinale *et al.* 2004) on sample points taken for co-culture experiments (Table 3.3) showed each co-culture was comprised of its component organisms and no contaminating organisms were detected.

Table 3.3 also compares the end-product synthesis patterns under aerobic and anaerobic conditions of the designed co-culture of *C. debilis* plus *C. thermocellum*, and monocultures of the two bacteria used in the designed co-culture against the initial B4-1 enrichment culture. The designed co-culture produced the same aerotolerant cellulolytic phenotype as the environmental enrichment culture B4-1 growing under aerobic conditions, with both co-cultures producing the end-products formate, acetate, lactate, ethanol, CO_2, and H_2 in varying concentrations at 72 h pi. Maintenance of aerobic conditions using shaking (Table 3.3) was confirmed visually (the pink colour of the resazurin dye) throughout growth, and at sample points by detection of excess oxygen using a GC.

The enrichment and designer co-cultures showed a similar response to oxygen for certain end-products. Both co-cultures display a decrease in formate and ethanol concentrations, and an increase in CO_2, acetate, and H_2 concentrations when compared to anaerobic cultures. Both the designer co-culture and B4-1 show a shift

towards lactate production, an aerotolerant fermentative pathway, under aerobic conditions when compared against the lactate production of the monoculture.

Further incubation under aerobic atmosphere (168 h pi) resulted in further metabolism of both substrate and fermentation end-products by the designer co-culture mostly to the respirative product CO_2. The reduction in concentrations of several end-products between 72 and 168 h pi in the aerobic co-culture is consistent with respiration of the fermentative end-products after the consumption of the sugars. Due to this apparent ability to consume end-products in co-culture, the ability to oxidize fermentation end-products was verified in pure culture using *C. debilis* (Table 3.3). Acetate and ethanol were oxidized, consistent with the reduction in O_2, while formate was only metabolised at higher levels in the presence of cellobiose.

3.6. Discussion

3.6.1. *Caldibacillus* Strain Comparison

First described as *Geobacillus debilis* in 2004 by Banat *et al.*, the type strain, DSM 16016 was characterized as Gram variable, rod shaped, spore forming, and obligatory aerobic organism with a temperature range of 50 – 70 º C. Upon re-evaluation of its taxonomic classification, it was renamed as *Caldibacillus debilis*, becoming the type strain for the new genus (Coorevits *et al.* 2012). Previous characterization of *C. debilis* strains showed the ability to grow aerobically on several substrates, including formate (Banat *et al.* 2004) in one strain, but none had been found to grow in the absence of oxygen. Our observed end-product profiles reveal

mixed fermentative and respiratory metabolism under aerobic atmosphere even though the type strain, 16016, was indeed an obligate aerobe (Table 3.1). While carbon sources were similar for both strains, aqueous end-product concentrations between strains were different (Table 3.1). When grown in static tubes in the presence of air, the redox indicator resazurin stayed oxidized throughout the experiment, both strains consumed oxygen but displayed incomplete respiration by the synthesis of acetate and formate. Strain 16016 (but not GB1) also synthesized lactate as a major end-product. GB1 produced ethanol under aerobic (resazurin oxidized to pink) or anaerobic conditions making it more attractive as an aerobic partner for CBP than 16016.

The decrease and subsequent elimination of formate production by GB1 in response to exposure of higher soluble O_2 (Table 3.3) concentrations likely stems from the fact that pyruvate formate lyase (PFL) is inactivated in the presence of O_2 (Takahashi *et al. 1987*). End-product data (Table 3.3) further suggests that PFL is used under anaerobic conditions, whereas pyruvate dehydrogenase (PDH) is most likely used under aerobic conditions, consistent with members of the closely related genus *Geobacillus* (Cripps *et al.* 2009). Analysis of the *C. debilis* 16016 genome revealed copies of genes encoding both of these enzymes. A copy of *adhe* an enzyme linked to high ethanol production (Peng *et al.* 2008) was also found in *C. debilis* 16016 but did not seem to be active under the growth conditions tested.

Typically, while under aerobic conditions, organisms produce CO_2 and H_2O, however, *C. debilis* produces acetate as well. Aerobic acetate production is commonly used to generate ATP and deal with excess acetyl-CoA generated by high carbon flux

through glycolysis (Farmer & Liao 1998). A unique characteristic that makes C. *debilis* GB1 desirable for biofuels production via CBP is low lactate production under all conditions tested, which is rare in wild-type thermophilic bacilli, such as *Geobacillus* species (Cripps *et al.* 2009, Tang *et al.* 2009, Danner *et al.* 1998). While both *C. debilis* GB1 and strain 16016 can grow aerobically using respirofermentative metabolism (Zigha *et al.* 2007), only GB1 maintains a low lactate phenotype.

Representatives of the thermophilic bacilli genera *Ureibacillus, Aneurinibacillus, Brevibacillus, Geobacillus,* and *Alicyclobacillus* (Fortina *et al.* 2001) have variable phenotypic characteristics regarding anaerobic metabolism, with both strictly aerobic and/or facultative anaerobic members being represented. Here we show a facultatively anaerobic strain within the genus *Caldibacillus*. Anaerobic fermentative metabolism make *C. debilis* GB1, with only low levels of lactate production, an interesting candidate for designer co-culture development to process lignocellulosic substrates in either aerobic or anaerobic conditions via CBP.

3.6.2. *Caldibacillus debilis* Plus *Clostridium thermocellum* Co-Culture

The enrichment culture B4-1 displayed an aerotolerant cellulolytic phenotype that is of interest for CBP (Chapter 2). Subsequent isolation and characterization of *C. debilis* GB1 from this enrichment demonstrated that *C. debilis* GB1 is most likely the organism lending functional aerotolerance to the enrichment. A co-culture of *C. debilis* GB1 and *C. thermocellum* 1237 was tested for cellulose degradation and ethanol production under non-reduced conditions. We compared the designed co-

culture with the original B4-1 enrichment containing *C. debilis* GB1 and an uncharacterized *C. thermocellum* strain as major components for their capacity to degrade cellulose. While both a pink colour and excess oxygen were observed throughout, *C. debilis* may reduce local concentrations of oxygen via respiration and/or via oxygen scavenging enzymes creating a reduced microenvironment for *C. thermocellum*. One possible requirement for this anaerobic micro-environment creation may be a solid substrate for biofilm creation (Zuroff & Curtis 2012). Indeed, there are several products generated from the co-cultures under aerobic conditions that require enzymes that are sensitive to oxygen, including H_2 and formate (Rydzak *et al.* 2009).

Figure 3.1 shows total ethanol, glucose equivalents consumed and ethanol yield per glucose. Previous studies of *C. thermocellum* growing on 1191 media on cellulose shows 6.1 mM of glucose equivalents are converted to end-products (Ronan *et al.* 2013, Biswas *et al.* 2015) in batch cultures, our experiments show 5.2mM glucose equivalents consumed. *C. thermocellum* under our conditions produces 4.2mM ethanol similar to other work in similar conditions (Islam *et al.* 2009, Biswas *et al.* 2015). The enrichment and defined co-cultures appear to act synergistically under aerobic conditions to allow for greater end-product production than either of the *C. debilis* or *C. thermocellum* monocultures. Synergies have been observed before in co-cultures containing *C. thermocellum* (He *et al.* 2011).

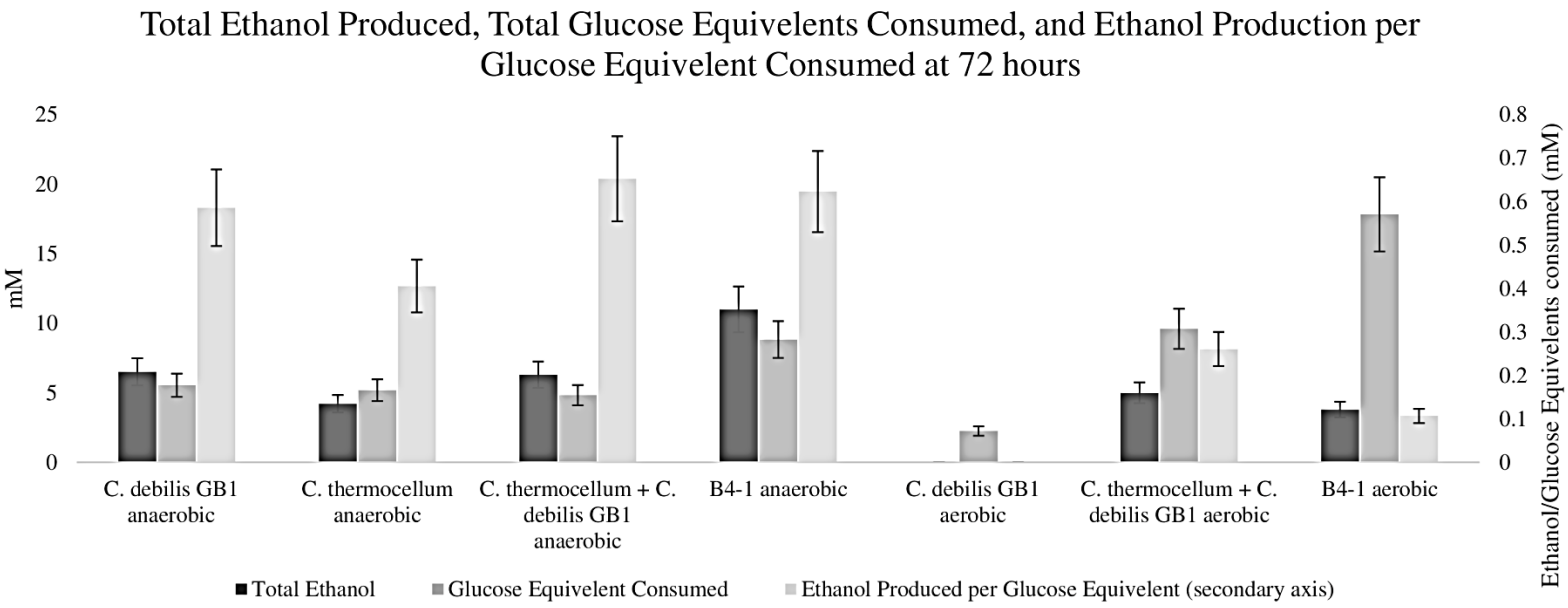

Figure 3.1. Comparison of total ethanol produced, total glucose equivalents consumed, and efficiency of ethanol produced per glucose consumed at 72 hours

Typically lignocellulosic ethanol production is rate-limited due to cellulose degradation rate (Levin *et al.* 2009, Lynd *et al.* 2005). The increase in total carbon consumed under co-culture conditions may be due to the ability of *C. debilis* to continue to metabolize cellobiose released through the action of the cellulosomes even after *C. thermocellum* has stopped growing due to low pH (under anaerobic conditions final pH~5.3, data not shown), alleviation of nutrient deficiencies, and/or consumption of end-products for utilization in respiration leading to a pH that does not limit growth of *C. thermocellum* (under aerobic conditions final pH of ~ 6.2, data not shown). Increasing total carbon consumed in CBP systems is a key element as an increase in total ethanol produced may enhance the economic viability of this process (Lynd *et al.* 2005).

Islam *et al.* (2006) showed high lactate production by *C. thermocellum* 1237 with high substrate loading, and during stationary phase. The shift to lactate production in *C. thermocellum* may be an indicator of cellular stress or of metabolic activity with limited growth (Rydzak *et al.* 2009). Cellular and/or oxidative stress may be important factors leading to high lactate in the designer and enriched co-cultures at 72 h pi. The genome of *C. thermocellum* DSM 1237 contains several annotated genes that may be involved in oxygen tolerance, including copies of alkyl hydroperoxidase, superoxide dismutase, and Mn-catalase. These genes may be necessary to deal with reactive oxygen species and reducing low levels of oxidative stress. It is possible that these can only be expressed while growing under microaerobic conditions, as provided by conditions of co-culture with *C. debilis.*

C. thermocellum has previously been shown to consume lactate (Rydzak *et al.* 2009). The ability of the co-culture to consume the fermentative products (lactate, acetate, ethanol) at 168pi appears to be an additive effect of the co-culture, since *C. debilis* GB1 appears to be capable of both acetate and ethanol oxidation (Table 3.4). While back consumption of ethanol is not ideal for CBP, the novelty of (micro) aerobic cellulosic degradation to produce ethanol makes it an interesting subject of study.

Table 3.4. Aerobic end-product (mmol/l of cell culture) consumption/production by *C. debilis* GB1 at 0, 72, and 168 hours of incubation at 60ºC on M-1191 medium (shaken 75rpm)1

Substrate	End products (mmol/L of cell culture)					O_2 consumed[3,6] (mmol/l of cell culture)

Uninoculated mixed end-product control[8]	2.4	2.1	2.6	2.7	BD	BD

[1]End-products produced and oxygen consumed from yeast extract control were subtracted from each condition (GB1 aerobically: CO_2=0.8 mmol/L of cell culture and O_2= 15 mmol/L of cell culture, GB1 anaerobically: 0.1 mM lactate, 1.5mM acetate and 0.4 mM formate), *C. thermocellum* did not produced any appreciable end-products from the media control [2]Addition of ~20.0 mM;[3] t_0 has 100.7 mmol/L of cell culture of O_2 available; [4]Standard deviation =<±10%; [5] Standard deviation =<±15%; [6]Standard deviation =<±10%[7] BD=below detection limit; [8] ~2.5 mM of each end-product and 1.1mM of cellobiose added where applicable.

While the aerotolerant phenotype is conserved in both the B4-1 enrichment culture and the designed co-cultures, there are some differences between the end-product synthesis patterns of the enrichment culture versus the designed co-culture. Comparison of the enrichment and designer cultures should be done with caution as there could be other undetected organisms within the enrichment culture (Chapter 2). Respiratory protection of an obligate anaerobe under aerobic conditions has previously been observed between *Clostridium phytofermentans* and yeast (Zuroff *et al.* 2013).

3.7. Conclusion

Previously described models for culturing of an obligate anaerobe and facultative anaerobe on a solid substrate includes oxygen depletion as the first step, followed by anaerobic fermentation (Miyazaki *et al.* 2008, Tran *et al.* 2010). In the current research, we observed simultaneous anaerobic fermentation and respiration. It is probable that the presence of *C. debilis* created an anaerobic micro-environment to allow *C. thermocellum* to ferment, even though the macro-environment remained aerobic (Table 3.3).

This study demonstrates that co-cultures containing only *C. debilis* and *C. thermocellum* possess both aero-tolerance and cellulolytic capabilities, even though *C. thermocellum* and the cellulosome are known to be aero-sensitive (Resch *et al.* 2013). This ability demonstrates potential CBP functionality under aerobic, anaerobic, or aero-transient conditions.

Chapter 4: Genome and proteome characterization of *Caldibacillus debilis* GB1 core metabolism under aerobic and anaerobic conditions[3]

4.1. Abstract

Caldibacillus debilis GB1 was isolated from a thermophilic aero-tolerant cellulolytic enrichment culture. GB1 shows a unique physiology of anaerobic growth when compared to the type strain Tf. There is a lack of representative proteomes of facultative anaerobic thermophilic *Bacillaceae*, exploring aerobic/anaerobic expression using high throughput techniques. The novel characteristics of GB1 compared to the type strain Tf, and ability to apply proteomic tools make GB1 of interest to study. The *C. debilis* GB1 genome was sequenced and annotated, and the proteome was characterized under aerobic and anaerobic conditions while grown on cellobiose. For the determination of the proteome, 2 dimensional liquid chromatography-mass spectrometry/mass spectrometry was used for protein separation and identification. iTRAQ (isobaric tag for relative and absolute quantification) based quantification was used to compare protein expression profiles, with special attention given to core metabolism and energy production and conversion pathways. The draft sequence of *C. debilis* GB1 contains a 3,340,752 bp chromosome

and a 5,386 bp plasmid distributed over 49 contigs. Under aerobic conditions, production of proteins in glycolysis and pyruvate fermentation associated pathway profiles were down-regulated. Simultaneously, peptides corresponding to enzymes of the tricarboxylic acid cycle, pyruvate dehydrogenase, the electron transport chain, and oxygen scavenging pathways showed increased amounts. Under anaerobic conditions, protein production in fermentation from pyruvate was consistent with the generated end-products: formate, acetate, ethanol, lactate, and CO2. Under aerobic conditions both the respiratory product CO_2 and significant levels of acetate were produced. Production of CO_2 and acetate is consistent with incomplete respiration. This result is corroborated in the proteome as many of the proteins associated with end-product production were detected in high abundance with the notable exception of lactate dehydrogenase (found in low amount under anaerobic conditions only), which is consistent with a low lactate production phenotype. Through a comparison with gene expression profiles from *Escherichia coli* and *Bacillus cereus*, we show that global regulation of core metabolism pathways is rather similar in thermophilic and mesophilic facultative anaerobes of the Phyla Proteobacteria and Firmicutes.

4.2. Introduction

Co-culturing of bacteria has been found to have potential applications in consolidated bioprocessing (CBP) for ethanol production from lignocellulosic substrates by providing stability for cellulose degrading anaerobes, such as *C. thermocellum*, through oxygen protection (Ronan *et al.* 2013, Chapter 3, Lü *et al.*

2013). The first step in understanding interplay and possible synergies between aero-tolerant cellulolytic co-cultures is characterization of both cultures individually. Wushke *et al.* (Chapter 2 and 3) isolated and described a novel strain of *Caldibacillus debilis*, strain GB1, which provided such protective capability.

The genus *Caldibacillus* is currently represented by one species, *Caldibacillus debilis*. *C. debilis*, is a thermophilic *Bacillaceae* highly related to, yet distinct from, the members of the genus *Geobacillus*. *Caldibacillus*, was recently separated from the genus *Geobacillus* based on 16S rRNA sequence similarity (93%) and physiological differences such as polar lipid composition (Coorevits *et al.* 2012). While the type strain is an obligate aerobe (Coorevits *et al.* 2012), one strain is capable of both aerobic and anaerobic growth, partial respiration under aerobic conditions, producing CO_2 plus acetate, and of synthesizing a mixture of fermentation end-products under anaerobic conditions, including lactate, ethanol, formate, acetate, and CO_2 (Chapter 3).

The genome of the type strain *C. debilis* Tf (DSMZ 16016) has been sequenced as part of the Department of Energy (DoE) tree of life project, but the strain has not yet been described beyond its initial isolation paper (Banat *et al.* 2004). Strain GB1 described within the present paper is highly related to Tf but, contrary to strain Tf, is capable of ethanol production and anaerobic growth (Chapter 3). Since the GB1 strain is a facultative anaerobe, we wanted to characterize aerobic and anaerobic metabolism in *C. debilis* GB1 using proteomics. Wushke *et al.* (Chapter 3) describe strain GB1 from a physiological perspective; as such this information will be used to contextualize the results observed using proteomics.

The regulation of core metabolic processes and differences in gene expression profiles created via a transition from aerobic to anaerobic conditions is an area that has been described in depth due to its importance to bacterial physiology (Nakano & Zuber 1998), but only on a limited number of organisms. Furthermore, incomplete respiration of sugars has not been an issue investigated in these previous studies. Since *C. debilis* GB1 produces acetate even under fully aerobic conditions (Chapter 3), it may act as an interesting organism to compare against. The present study employs high-throughput, genome sequencing and annotation, proteomic analysis, to characterize aerobic and anaerobic catabolic pathways of *C. debilis* GB1. *C. debilis* GB1 shows a unique end-product profile compared to the type strain Tf and incomplete respiration. There are very few examples of proteomes exploring aerobic/anaerobic regulation in facultative thermophilic member of the *Bacillaceae* using liquid chromatographic-mass spectrometry techniques. Feng *et al.* 2007 employed classical 2D-page proteomic techniques on *Geobacillus thermodenitrificans* and discuss the genome and proteome in relation to aerobic and anaerobic metabolism, the authors did not generate their proteomes to investigate aerobic/anaerobic cross state changes. Since aerobic/anaerobic cross state comparisons were not preformed they could only make statements on the presence or absence of proteins with regard to respiration and fermentation. Because changes seen in expression within a proteome are also seen at the transcriptomic level, proteomes and transcriptomes have been directly compared before within the same organism (Munir *et al.* 2016, Fu *et al.* 2015) and between organisms (Verbeke *et al.* 2013). In order to understand aerobic and anaerobic metabolism of *C. debilis* in a broader

context, a comparison against another organisms is pertinent. Therefore a comparison of the *C. debilis* GB1 proteome set to a published *E. coli* K-12 transcriptomic data set (Partridge *et al.* 2006) under both anaerobic and aerobic growth conditions was done. We also discuss the *C. debilis* GB1 data set in light of aerobic and anaerobic regulation reported by Weber *et al.* (2006) for *E. coli* and by Van der Voort *et al.* (2009), and Nakano & Zuber (1998) for *Bacillus cereus.* The resultant comparison of organisms with similar core metabolisms and gene complements revealed that global regulation is similar between mesophilic and thermophilic representatives of the Firmicutes and Proteobacteria, respectively.

4.3. Materials and Methods

4.3.1. Cell Culturing and Harvesting

C. debilis strain GB1, DSM 29516, described in previous work (Chapter 3, Chapter 2) was grown on modified 1191 (M-1191) medium (Chapter 2, Islam *et al.* 2006) for all experiments. The M-1191 medium contained lower concentrations of yeast extract (0.76 g/L) compared with standard 1191 medium, and the medium pH was adjusted to 7.2. Sealed Balch tubes (26 mL) from Bellco Glass Inc. (Vineland, NJ) and 1 L Corning bottles supplied from Fisher Scientific (Toronto, ON), were used to carry out experiments. Anaerobic and aerobic environments in Balch tubes and Corning bottles were prepared as previously described by Wushke *et al.* (Chapter 3). Prior to each experiment, cells were passaged once under the relevant growth condition to allow adaption. All cultures were grown at 60 ºC with shaking at 75 rpm.

During aerobic growth, excess oxygen in the headspace of the cultures was periodically determined by GC analysis (Chapter 3). Throughout growth, a higher redox of the medium consistent with aerobiosis was determined visually during cell growth under relevant conditions thanks to the pink colour of resazurin dye in the medium. Growth curve experiments were carried out in triplicate using a 0.2% inoculum.

Cells grown for proteomic experiments were carried out in duplicate using a 0.2% inoculum. Cells were harvested at ~40μg total protein/mL corresponding to early-exponential phase. Presents of oxygen under aerobic conditions was confirmed via GC and the production of end-products consistent with previous experiments was confirmed via HPLC. At this point in growth, the biomass had reached 50 μg total protein per mL as measured by the Bradford protein assay method (Bradford, 1976). Fifty mL of culture were harvested by centrifugation at 7000 x g for 20 minutes at 4ºC to create cell pellets. These were stored at -80ºC for further processing.

4.3.2. DNA Isolation and Processing

For genomic DNA, a Promega Wizard Genomic Extraction Kit (Promega) was used and protocol followed as described by the manufacture. DNA was sent for sequencing at McGill University and Genome Quebec Innovation Centre using the 454s-GS-FLX-Titanium shotgun sequencing method similar to methods used by Verbeke *et al.* (2013). To improve gap closure and obtain higher quality data, the genome was re-sequenced using Illumina HiSeq 2000 paired end technology.

Multiple assembly pipelines combining both 454 and Illumina data were evaluated (Verbeke *et al.* 2013). Based on statistical metrics, we chose Newbler v2.6 for our assembly (Trong *et al.* 2009), which resulted in a genome of 3,340,752 bp distributed on 49 contigs, with a minimum depth of coverage of 19X. The sequence was then submitted to the Joint Genome Institute's Integrated Microbial Genomes Expert Review (IMG/ER) platform for gene annotation (Markowitz *et al.* 2008). Anomalies were identified and corrected manually. Further corrections were made by use of a naive assembler to identify and correct possible sequence errors based on the proteomic data (Verbeke *et al.* 2013). The final genome annotation was submitted to the National Center for Biotechnology Information (NCBI) under the GenBank accession number AZRV00000000.

4.3.3. Preparation of Cells for Protein Extraction

Cells were washed 3 times in 10 mL PBS buffer and frozen at -80 ºC. Cells were re-suspended in 10 mL SDT buffer (4% w/v SDS, 100 mM pH 7.6 Tris-HCl, 0.1M DTT), boiled for 15 minutes (min), and sonicated for 2 min continuously (Fisher Sonic Dismembrator-model 300). Unlysed cells and cell debris were removed by centrifugation at 13,500 x g for 15 min at room temperature, and the supernatant was collected. Amicon ultra Falcon tube centrifugation units, with a 10 kDa filter, were used to concentrate the protein lysate, which was washed 3 times with 10 mL of filter sterilized UA solution (8M urea in 0.1 M tris/HCL pH 8.5) at 4000 x g for 30 min and the flow-through discarded. Proteins were alkylated using 5 mL of IAA

solution (UA solution with iodoacetamide 0.5 M added) for 15 minutes. IAA solution was centrifuged to remove it from the Amicon ultra falcon tube centrifugation unit. The alkylated protein lysate was rinsed 2 times with 5 mL UA solution using centrifugation at 4000 g separated the liquid from the alkylated protein lysate, the flow through was discarded. ABC solution (ammonium bicarbonate 0.05 M) was used to re-suspend protein, and 50 µL were collected for total protein estimation using a NanoDrop and Bicinchononic Acid (BCA) Protein Assay Kit (Pierce Biotechnology, Rockford, IL). Total protein was then concentrated using centrifugation 4000 x g for 30 min, and re-suspended in a final working volume of 2 mL using ABC with trypsin added at a 1:10 ratio (trypsin: total protein). Trypsinization was carried out for 10 hours (h) at room temperature. Then 10% trifluoroacetatic acid (TFA) (20 µL) was added to acidify the sample, after which the sample was added to a filtration unit placed on a fresh Falcon conical tube, centrifuged at 4000 x g for 30 min, and the flow though collected. The filter washed using 200 µL of 0.5 M NaCl, centrifuged at 4000 x g for 30 min and the flow through collected. Peptide concentration was estimated using the NanoDrop, samples were frozen at -80 ºC for 24 hours, dried and concentrated using a roto-evaporation (Savant Speedvac-sc110). Samples were re-suspended in 270 µL of 0.1% TFA and desalted using C18 X-Terra column (1 × 100 mm, 5 µm, 100 Å; Waters Corporation, Milford, MA, USA) with 50% acetonitrile used to elute peptides. Desalted samples were frozen at −80°C and concentrated using roto-evaporation. Two biological samples (100 µg) from aerobically and anaerobically grown cells were then labelled with isobaric Tags for Relative and

Absolute Quantitation (iTRAQ) reagent (Applied Biosystems, Foster City, CA, USA) following the protocol described by the manufacturer.

4.3.4. Mass Spectrometry

Instruments and methods used for proteomic analyses were previously described (Rydzak *et al.* 2012). Two-dimensional liquid chromatography-mass spectrometry/mass spectrometry was used for peptide separation and identification. A QStar Elite mass spectrometer (Applied Biosystems, Foster City, CA) was used in standard MS/MS data-dependent acquisition mode with a nano-electrospray ionization source. The 1 second(s) survey MS spectra (m/z 400–1500) were collected, followed by three MS/MS measurements on the most intense parent ions (80 counts/s threshold, +2 to +4 charge state, m/z 100–1500 mass range for MS/MS), using the manufacturer's "smart exit" settings and iTRAQ settings.

4.3.5. Database Search, Protein Identification, and Statistical Analysis

Raw spectra WIFF files, a QSTAR file format, of unlabeled peptides were treated using standard script (Analyst QS 2.0) to generate text files in Mascot Generic File format (MGF) (Cottrell *et al.*1999) and ProteoWizard to generate mzML files (Kessner *et al.* 2008) MGF files containing the MS/MS spectra information for all 4 fractions were concatenated and submitted for protein identification using Global Proteome Machine's (GPM) X!Tandem (Craig *et al.* 2004) and an in-house, GPU-based peptide identification engine described by McQueen *et al.* (2012).

Standard QTOF settings were used for the search: 100 ppm and 0.4 Da mass tolerance for parent and fragment ions, respectively. Permitted amino acid modifications included constant carbamidomethylation of Cys. The XML output file from an X!tandem search and its corresponding iTRAQ reporter intensity collection is archived at: http://hs2.proteome.ca/gpm/archive/cdeb/BASERESULTS.xml.gz and http://hs2.proteome.ca/gpm/archive/cdeb/BASERESULTS-tic.gz. The iTRAQ reporter intensities as well as total ion current (TIC) on a peptide level were summed into their source proteins. TIC represents the summed intensity across the entire range of masses being detected at every point in the analysis. These sums were log2 transformed for simple differential analysis (Rydzak *et al.* 2012). All 3264 of the protein coding genes in the genome were used in the data dependent identification of MS/MS spectra. X!Tandem used a survival function of the 6732 assigned spectra to give an estimated peptide spectrum match false discovery rate (FDR) of 1.8% (Fenyö *et al*. 2010). Each protein measurement required a minimum of two peptide spectrum matches. We used our in-house data analysis system UNITY (Fu *et al.* 2015) to analyse and manipulate our proteomic data. The reporter ion (iTRAQ tag) intensities for each tryptic peptide identified (with expectation values < −1.5) were transformed by the log2 of the ratios (Z0 = tag116/tag114, Z1 = tag117/tag115, R0 = tag115/tag114, and R1 = tag117/tag116) to build overall peptide population distribution histograms, where aerobically grown replicates were labeled with tags 114 and 115, respectively, and anaerobically grown replicates were labeled with tags 116 and 117, respectively. Peptide level Z-scores are mapped as the distance from the population mean in units of standard deviation; initial protein-level Z-scores are

averages of the member peptide Z-score values. The Z-scores (R0, R1) contain information about the stability across biological replicates at the same growth state, while Z0 and Z1 represent the differences between the 2 growth states.

A simple algorithm was used to combine these with the differential data in (Z0,Z1), expressed as the difference between the magnitudes of vectors from the origin to points (Z0,Z1) and (R1,R0), scaled by the widths of their peptide histogram distributions (Rydzak *et al.* 2012). Then Z0, Z1, R0, R1 were normalized to give $Z0_{net}$, $Z1_{net}$, $R0_{net}$, and $R1_{net}$, respectively. The sign of the transformed values were determined by the angle subtended by a vector from the origin to the point ($Z0_{net}$,$Z1_{net}$). We denote this combined value of the vector difference as Zmag. A Zmag >± 1.65, represents the outer 10% of population, while a Zmag > ± 1.28, represents outer 20% of population of measured protein differences. These can be converted to fold change difference by taking the 2 to the power of the Zmag, as described by Rydak *et al.* (2012), with a 1.65 and 1.28 Zmag representing a 3.2 and 2.4 fold change respectively.

To enable analysis of smaller Zmag differences, we used a function, W_{stat}, to evaluate the statistical significance of a two-state two-replicate dataset on a protein-by-protein basis. We derived an overall measurement-system quality as:

Quality = (SD (Z0) / SD (Z1)) / (SD (R0) / SD (R1))

Where SD = Standard deviation

Then, to exploit this at an individual protein level, we used the following formula:

W_{stat} = Quality* √ ($Z0net^2$+$Z1net^2$)/ √ ($R0net^2$+$R1net^2$),

Where Z0net and Z1net are normalized Z0 and Z1.

The W_{stat} value denotes the "signal to noise" (S : N) ratio of the vector magnitudes of each respective cross-state and intra-replicate normalized value, scaled by the overall system quality. Monte-Carlo models were used to derive a function relating the W_{stat} value to the FDR. In our analysis, proteins with a $W_{stat} > 2.8$ have a FDR of 10% or less.

4.3.6. Comparison of *C. debilis* GB1 Proteome with *E. coli* K-12 Transcriptome

We compared our proteomic set from *C. debilis* GB1 to a transcriptomic data set from *E. coli* K-12 (Partridge *et al.* 2006) using the in-house data analysis system called UNITY (Fu *et al.* 2015, Verbeke *et al.* 2014). We chose the *E. coli* K-12 data set as it was in a machine readable format compatible with our methods, and compared the data sets using Z-scores and Zmag expression changes under aerobic and anaerobic conditions as these values are scaled against their mean, allowing us to make direct comparisons. Using data from Partridge *et al.* (2006) in our analysis allowed us to look at expression patterns that were not overtly discussed in the cited paper, and allowed us to compare their interpretation with ours.

4.4. Results and Discussion

4.4.1. General Genome Features

The *C. debilis* GB1 genome consists of a 3,340,752 bp draft genome (and a 5,483 bp plasmid) distributed on 49 contigs with a GC content of 51% (Appendix D). The GB1 genome encodes a total of 3,374 annotated genes, 3,264 protein coding genes, 110 RNA genes, including 8 ribosomal rRNA genes, and 85 Transfer (t)RNA genes. Gene encoding sequences account for 79.8% of the genome. Putative functions were assigned to 2,450 Open Reading Frames (ORFs), with the majority of the remaining 814 ORFs designated as hypothetical or conserved hypothetical gene products. There are 25 putative transposase associated genes. A putative origin of replication, *oriC*, was identified based on structures homologous to origins of replication identified in other Firmicutes. A DnaA-box like sequence (Cdeb_00348) and several genes encoding DNA replication enzymes that are known to be associated with *oriC*, such as DNA gyrase subunits A and B (Cdeb_00344, Cdeb_00343), and a primary replicative helicase (Cdeb_00367), were identified in close proximity to one another. This annotated genome was used for the analysis of the proteomes described below.

4.4.2. Growth Characteristics at the Proteomic Sampling Point

Cells were grown aerobically and anaerobically to early exponential phase to get representative protein profiles for eventual proteomic analyses. For aerobic conditions, cultures were shaken at 75 rpm and continuous presence of O_2 in the headspace was confirmed by GC analysis. The pH of the aerobic culture during early exponential phase was 6.95. Conversely, anaerobic conditions entailed flushing O_2 with N_2 gas and shaking at 75 rpm. The pH of the anaerobic culture during early exponential phase was 6.85. End-product analyses indicated that under anaerobic conditions, *C. debilis* GB1 synthesized lactate, formate, acetate, and ethanol, as previously described by Wushke *et al.* (Chapter 3). Wushke *et al.* (Chapter 3) show that aerobic cultures synthesized CO_2 and acetate, suggesting that their metabolism was carrying out incomplete respiration. The end-product profiles of cells grown for proteomics measurements matched the end-product profiles of those grown in chapter 3 as measured by HPLC and GC under aerobic and anaerobic conditions, under aerobic conditions O_2 was present and in excess, further the resazurin media redox indicator was pink confirming oxidizing conditions. Growth curves showing the harvesting points for total protein extractions for proteomics analyses are in Figure 4.1. As previous work by Wushke *et al.* (Chapter 3) detailed the physiology with respect to end-product production under aerobic and anaerobic conditions, the proteomic data could be placed in physiological context.

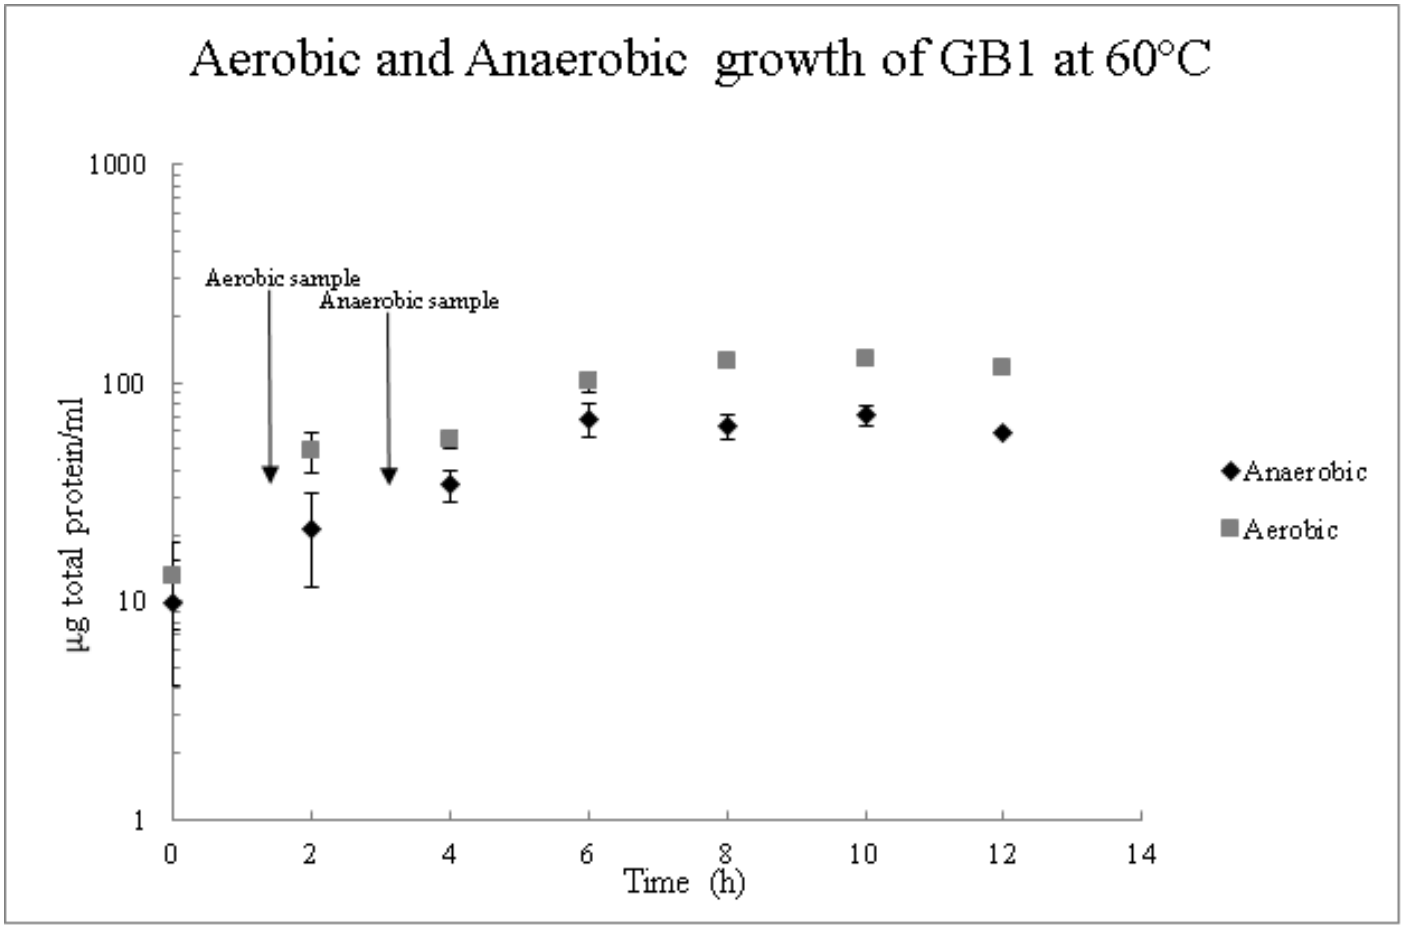

Figure 4.1. ***Caldibacillus debilis*** **GB1 growth curves at 60ºC shaken 75 rpm aerobically and anaerobically**

4.4.3. General Features of the Proteomes

Relative abundance of individual proteins between aerobic and anaerobic expression profiles were examined by z-score (Zmag is the combined vector of the 2 z-score replicates) and $\log_2$ (TIC). The Z0, Z1, R0, and R1 histograms showing their distributions, average, and standard deviations are in Figures 4.2, 4.3, 4.4, 4.5 and Table 4.1. Out of the 3,264 protein coding genes within the genome, 1,144 were detected in the pooled TICs (all 4 samples). 438 of the detected proteins could not be quantified as they were not detected in under both conditions and in both replicates. 706 could be quantified between conditions and given Zmag scores. These are listed in Table C.1, Appendix C and identified by their COG categories. Of the 706 proteins assigned Zmag values, 220 had W_{stat} values > 2.8, and therefore a FDR rate of < 10%. Correlation between the Z-scores of the cross state replicates (Z0net and Z1net in Figure 4.6) was good, with an R^2 of ~ 0.83.

The following sections describe the differences in protein amounts of specific pathways associated with catabolism in aerobically and anaerobically grown *C. debilis* GB1. For comparison and subsequent discussion (see section 4.4.12), transcriptomic data from *E. coli* K-12 (Partridge *et al.* 2006) for the equivalent functional genes are presented side-by-side on the same scale. An overview of the pathways with their average normalized expression values for each pathway in *E. coli* K-12 and *C. debilis* GB1 can be found in Table 4.2

[2]Z-score is the expression difference between anaerobic/aerobic conditions of *E.coli* K-12 transcriptome;

4.4.4. Tricarboxylic Acid Cycle

The Tricarboxylic acid (TCA) cycle is an important source of reduced equivalents for ATP synthesis during aerobic growth, and should be highly expressed aerobically when compared to anaerobic conditions. On the basis of $\log_2$(TIC) the TCA cycle enzymes were highly expressed, with many being above the 50th percentile of expressed proteins (Table 4.1A). Upon deeper analysis, six enzymes (or subunits thereof) involved in the TCA cycle were highly (> 1.65) up-regulated and one was moderately up-regulated (> 1.28) in *C. debilis* GB1 cells under aerobic conditions (Table 4.3). Additionally, enzyme subunits *e.g.* Cdeb_02130, Cdeb_02131 of the TCA cycle were contiguous in the genome and showed similar changes with a Zmag of 3.34 and 2.29 respectively in the proteomes. When expression level differences were averaged for the entire TCA cycle (Table 4.2), it became clear that the TCA cycle was significantly up-regulated under aerobic conditions. Table 4.3 also illustrates the importance of grouping all of the elements of a pathway. This allows one to observe more subtle regulation at the pathway level. Indeed several of the changes seen, while they were rather large, were below our significance threshold cut-offs (± 1.65 and ± 1.28) at the individual gene level for the present experiments with *C. debilis*. However, the average Zmag values of the pathway clearly demonstrate an increase in the pathway expression of TCA cycle enzymes under aerobic conditions.

[1]Zmag is the difference in expression between anaerobic/aerobic conditions of *C. debilis*; [2]Z-score is the expression difference between anaerobic/aerobic conditions of *E.coli* K-12 transcriptome; [3]TIC= Total ion current.

4.4.5. Glycolysis

Typically aerobic conditions are associated with down-regulation of glycolysis when compared to growth under anaerobic conditions (Partridge *et al.* 2006, Van Der Voort *et al.* 2009). However, no enzymes in *C. debilis* were highly down-regulated (<-1.65) or down-regulated moderately (< -1.28; Table 4.3). Nevertheless, when the Zmag values were averaged over the entire pathway (Table 4.2), a depression in the glycolysis pathway could be clearly observed. Furthermore, several glycolysis pathway proteins, encoded by genes located next to each other, and which may constitute operons, showed similar changes, indicating their expression levels may be linked. The $\log_2$TIC of the proteins involved in glycolysis indicate that these proteins are highly represented within the proteome, similar to other facultative anaerobic organisms (Van Der Voort *et al.* 2009). Under our conditions, aerobic metabolism of glucose yields higher amounts of energy and therefore, the cells need to flux less glucose when compared to anaerobic conditions to yield the same amount of conserved energy (Verbeke *et al.* 2014).

4.4.6. Pyruvate Metabolism and End-Product Synthesis

Pyruvate metabolism is essential for both aerobic growth and anaerobic growth. Typically the genes associated with fermentation are expressed anaerobically, while some genes linked to respiration (e.g. PDH) could be utilized both aerobically and anaerobically. Only two of the enzymes involved in pyruvate metabolism, alcohol/aldehyde dehydrogenase (ADHE) and aldehyde dehydrogenase (AlDH),

showed a high degree of down- regulation (<-1.65) under aerobic conditions (Table 4.3). An averaging of Zmag values in detected enzymes associated with pyruvate fermentation, excluding pyruvate dehydrogenase (PDH), shows an overall down-regulation of pyruvate fermentation pathways (Table 4.2). PDH is omitted due to its link with respiration (Nakano *et al.* 1997). Overall, we expect a depression in pathways linked to end-product synthesis and fermentation under aerobic conditions, as is typically observed in other facultative anaerobes (Van Der Voort *et al.* 2009). *C. debilis* produces acetate under aerobic growth conditions; therefore, we expect the components of pyruvate fermentation, such as phosphotransacetylase (PTA) and acetate kinase (AK), to show less of a depression aerobically. Indeed, *C. debilis* PTA and AK did not show Zmag changes above the moderate threshold of -1.28 with Zmag values of -0.09 and -0.43, respectively.

Pooled $\log_2$ (TIC) gives us a general estiment of protein proportiality within the cells regardless of conditions. We expect high pooled $\log_2$(TIC) values for the enzymes leading to the production of major end-products. When end-products synthesized under anaerobic versus aerobic conditions (Chapter 3) are considered, they appear to be consistent with protein expression and amounts. Enzymes associated with the synthesis of formate (Pyruvate formate lyase (PFL) and PFL activating enzyme: Cdeb_01638, Cded_01637), acetate (acetate kinase (AK): Cdeb_03124, phosphotransactylase (PTA):Cdeb_00469), and ethanol ADHE: Cdeb_01397) all had pooled $\log_2$(TIC) values above the 50^{th} percentile of expression. Trace amounts of lactate were formed. Lactate dehydrogenase (LDH: Cdeb_02710) LDH was observed just above the detection threshold under anaerobic conditions, and under the detection

threshold aerobically; therefore, its expression difference could not be determined through this proteomic analysis. Low expression of LDH, and the fact that when it is detected it has a very low log2(TIC), is consistent with the relatively low amounts of lactate detected compared to other end-products.

4.4.7. Oxygen Respiration

The *C. debilis* GB1 genome encodes the enzymes necessary for respiration including complex I (NADH:ubiquinone oxidoreductase), II (succinate dehydrogenase), III (cytochrome bc_1 complex) and IV (cytochrome c oxidase). However, we could not calculate Zmag for subunits of Complex I as peptides associated with proteins in Complex I did not meet our detection criteria threshold. We could calculate Zmag for several of the other components including genes encoding for Complex II:fumarate reductase (Cdeb_02776, Cdeb_02777), Complex III:cytochrome bc1 complex (Cdeb_00880), complex IV:cytochrome C oxidase (Cdeb_02460, Cdeb_00920, Cdeb_00921), as well as subunits for the high affinity Cytochrome bd oxidase complex (Cdeb_01033, Cdeb_01034), and the ATP synthase (Cdeb_00529-Cdeb_00533) proteins. Four individual genes encoding components of the electron transport chain were highly up-regulated (> 1.65), and one was moderately up-regulated (> 1.28), under aerobic conditions (Table 4.3). The overall combined $\log_2$TIC of enzymes associated with respiration were highly expressed, at levels similar to other core metabolic pathways, such as glycolysis or the TCA cycle. Several of the genes for which we were able to calculate Zmag values are found next

to each other in the genome, possibly forming operons, and shared similar trends in changes of expression levels under anaerobic versus aerobic conditions.

4.4.8. Reactive Oxygen Species Protection

Facultative anaerobes typically contain a gene complement for protection from reactive oxygen species (ROS) (Engelmann *et al.* 1995). The *C. debilis* GB1 genome was found to encode catalases, as well as superoxide dismutases and peroxidases. We were not able to quantify a Zmag for superoxide dismutase as it did not meet our detection threshold criteria. Although two distinct Mn-catalase genes are encoded in the GB1 genome, only one Mn-catalase (Cdeb_01630) was detected in the proteome (Table 4.3), but this gene product was not significantly up-regulated under aerobic conditions. Detection of only one catalase is consistent with other work where the copy of catalase being expressed at the transcriptome level is determined by whether the cells are in stationary or exponential growth phase (Engelmann *et al.* 1995). Two copies of peroxiredoxin were also detected in the proteome, but the expression levels of these gene products did not change significantly under aerobe versus anaerobic conditions.

The combined $\log_2$TIC of the Mn-catalase expression at high levels is consistent with an organism that is prepared for oxidative stress. The $\log_2$TIC of the peroxiredoxin gene products were much lower, indicating catalase may be the primary driver of hydrogen peroxide flux. In general, gene products related to ROS protection would be expected to increase average Zmag under aerobic conditions such as in

Bacillus cereus as studied by Van der Voort *et al.* (2009). However, likely due to the small number of proteins observed, this relationship was not detected

4.4.9. Pyruvate Dehydrogenase

Pyruvate dehydrogenase (PDH) can be associated with either respiratory or fermentative functions. Facultative anaerobes such as *E. coli*, and members of the genus *Bacillus*, also use alternative means of generating acetyl-CoA from pyruvate, such as PFL, and up-regulate PDH under aerobic conditions (Nakano *et al.* 1998, Partridge *et al* 2006). Typically PDH is encoded within operons; *C. debilis* possesses 3 operons. In *C. debilis* GB1, out of the 8 PDH operon associated genes for which we could calculate Zmag, only one PDH operon associated subunit (table 4.3). Cdeb_02439, showed high up-regulation (Zmag> 1.65), while a moderate increase (>=1.28) was observed for one other PDH operon associated gene product (Cdeb_02440) under aerobic conditions. Operon (Cdeb_02441-Cdeb_02438) also corresponds to the subunits that show the most change in Zmag when compared to other PDH operons. Although *C. debilis* GB1 genome appears to encode 3 full PDH operons, only one (Cdeb_02441-Cdeb_02438) is predominantly expressed, as indicated by the pooled $\log_2$(TIC) scores (table 4.3).

4.4.10. Other Highly Differentially-Expressed Pathways

While our primary focus was to elucidate core metabolism pathways in *C. debilis* GB1 under aerobic versus anaerobic conditions, we also observed other pathways that were highly differentially expressed aerobically (> ± 1.65). When arranged by KEGG category (Table 4.4) through the gene annotation program used, pathways with at least one gene product were assigned to a KEGG map and an overall Zmag change was calculated. As this is a broad analysis for the purpose of highlighting potential differences, the core aspect of this is to emphasize filled maps with possible large expression changes. We defined well filled maps as having 5 or more protein measurements. Many of the KEGG maps that were well filled, were found to undergo a high degree of change: an increase in aerobic expression Zmag> +1.65: fatty acid elongation, cysteine and methionine metabolism, carbon fixation pathways in prokaryotes, citrate cycle (TCA cycle), glyoxylate and dicarboxylate metabolism. Some of Zmag values from these KEGG maps can be misleading due to a large number of shared genes, for instance carbon fixation pathways in prokaryotes, and glyoxylate and dicarboxylate maps share a significant number of enzymes with the TCA cycle KEGG map. We did not see KEGG maps with a fill of 5 or more with a decrease in aerobic expression Zmag<-1.65. When COG categories are considered (Table 4.5) for the *C. debilis* dataset, the energy production and conversion category was the most changed with 16 proteins highly up-regulated aerobically and 2 highly down-regulated aerobically (± 1.65) out of 111.

Table 4.4. Overview of KEGG pathway regulation organized by largest to smallest # of proteins detected in map

Zmag[1,2]	# of proteins detected in map	# Genes in map	# Total possible genes in map	KEGG ID	PATHWAY

Z "Cytoskeleton"	0	0	0
Total changes	42	34	3522

Proteins with a <+1.65 or >-1.65 change in Zmag were considered up/ down regulated at a high level. This corresponds to the outermost 10% change corresponding to a fold difference of 3.2. Most changed COG category is **bolded**.

4.4.11. Core Metabolism Overview

Detailed analysis of the individual pathways (section 4.4.12-4.4.17) above is corroborated by KEGG map analysis in Tables 4.4 where filled pathways involved in aerobic and anaerobic metabolism are among the most changed. COG analysis also corroborate our detailed pathway analysis, Table 4.5 shows energy production and conversion has a high degree of changing expression as would be expected in an organism switching from respiration to substrate level phosphorylation.

A list of proteins with their corresponding W_{stat} value can be found in Table 4.1A, filtering W_{stat} by a 2.8 threshold give a higher quality (higher statistical confidence) data set. However, filtering our results leads to significant depopulation of pathways of interest; therefore, we found looking at significant changes of Zmag not filtered by W_{stat} gave us more usable results. Importantly, the overall pathway regulation patterns observed in Figure 4.7 are corroborated by the higher quality W_{stat} values. Figure 4.7 shows which core metabolism pathways were up- and down-regulated in a general sense, for *C. debilis* GB1 under aerobic versus anaerobic conditions. Each individual pathway is described in detail in the figure legend below.

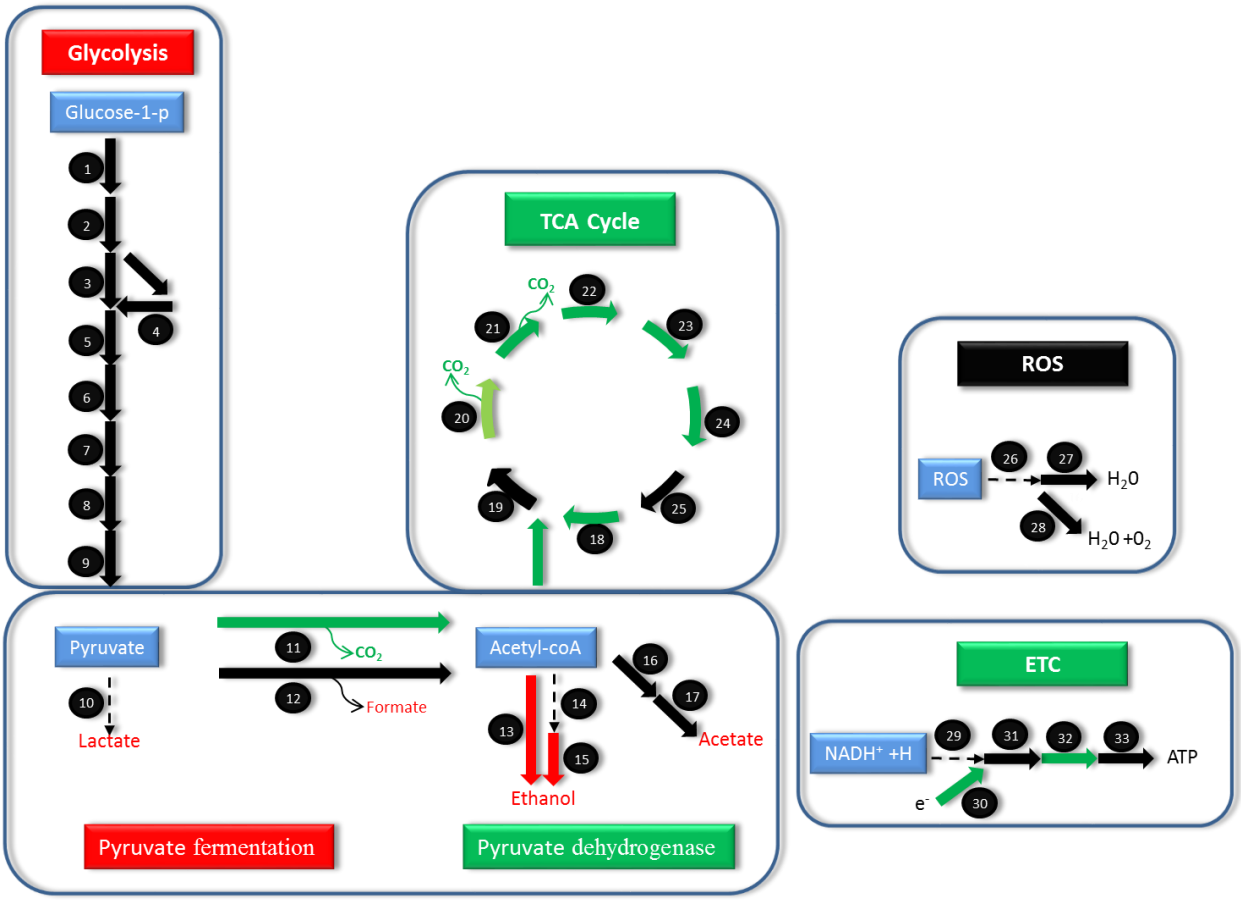

Figure 4.7. Comparative proteomic overview of core metabolism under aerobic vs anaerobic growth conditions in *C. debilis* GB1.

Individual protein colour scheme: Change of Zmag in one or more copies/subunits= ± 1.28: + light green(- orange); Change of Zmag in one or more copies/subunits=± 1.65: + dark green(- red); No statistically significant change -1.28<Zmag<1.28 black; Corresponding genes present in the genome, but no Zmag information= dash line.

Pathway colour scheme: Whelch's t-test was preformed to determine if there was a significant change in average Zmag at the pathway level, pathways that are found to increase significantly (p value< 0.05) are written in dark green, pathways that are found to decrease significantly (p value< 0.05) are written in red.

End-product colour scheme: Whelch's t-test was performed on end products produced under each condition (data taken from Chapter 3, end products that are found to increase significantly (p value< 0.05) are written in dark green, end products that are found to decrease significantly (p value< 0.05) are written in red.

Enzymes: 1) G-6-P isomerase, 2) 6-p phosphofructoskinase, 3) f-1, 6-P aldolase, 4) triose isomerase, 5) Glyceraldehyde 3-P dehydrogenase, 6) 1,3-P bisphosphoglycerate kinase, 7) Phosphoglycerate mutase, 8) enolase, 9) pyruvate kinase, 10) lactate dehydrogenase, 11) pyruvate dehydrogenase, 12) pyruvate formate lyase, 13) alcohol/aldehyde dehydrogenase, 14) aldehyde dehydrogenase, 15) alcohol

dehydrogenase,16) phosphotransacetylase, 17) acetate kinase, 18) citrate synthase, 19) aconitate hydratase, 20) isocitrate dehydrogenase, 21) alpha-ketogultarate dehydrogenase, 22) succinyl-CoA synthase, 23) succinate dehydrogenase, 24) fumerate hydratase 25), malate dehydrogenase 26), superoxide dismutase, 27) peroxidases, 28) catalase, 29) complex I, 30) complex II, 31) complex III, 32) complex IV, 33) ATP synthase/complex V

4.4.12. Comparison against the *E. coli* K-12 data set

Proteomic or transcriptomic have been utilized to make comparisons between species and between different published datasets (Verbeke *et al.* 2013, Fu *et al.* 2015). Comparing proteomes directly against transcriptomes has also been done and changes in expression were corroborative (Yang et al. 2012, Hahne *et al.* 2010, Munir *et al.* 2016) Since a suitable *Bacillus sp.* raw data set that could be integrated directly using our methods was not found, the *E.coli* K-12 data set provided a dataset that was compatible, and could be incorporated into our analysis engine. The difficulty in finding a closer related data set highlights the importance of reporting data in a similar fashion. Nevertheless, direct comparison against a well-studied organism from a different phylum, such as *E. coli* gives the ability to compare and contrast aerobic and anaerobic regulation across widely divergent organisms.

The physiological similarities between *C. debilis* GB1 and *E. coli* K-12 (both facultative anaerobes, with similar core carbohydrate metabolisms), the similarities between the experimental conditions used (anaerobic to aerobic conditions) and the compatibility of their data presentation with our in-house analysis system made the *E. coli* K-12 transcriptome dataset published by Partridge *et al.* (2006) an ideal model to compare with our *C. debilis* GB1 data set. Typically, there are major changes in gene and gene product expression when cells grown under aerobic and anaerobic conditions are compared, and these expression changes are usually associated with pathways involving energy production and conversion such as glycolysis, TCA, respiration, and pyruvate metabolism in *E. coli* K-12 (Partridge *et al.* 2006, Weber *et al.* 2006).

Glycolysis in *C. debilis* did not appear to change significantly at an individual enzyme level as protein expression changes were not as great as was expected on the basis of the *E. coli* K-12 data set by Partridge *et al.* (2006). At the pathway level, however, the direction of the changes in expression was consistent. Overall, down-regulation of glycolysis is consistent with an increase in energy per glucose and a reduction in glucose flux as seen in *E. coli* K-12 data set (Partridge *et al.* 2006).

At the pathway level, we noticed TCA expression under aerobic conditions in *C. debilis* was highly up-regulated and was similar to *E. coli* K-12 data set by Partridge *et al*. (Partridge *et al.* 2006). Overall an increase in flux through the TCA cycle is beneficial under aerobic conditions since the electrons generated can be used for ATP production via the ETC. Overall pyruvate fermentation was found to be consistent with aerobic growth of *E. coli* K-12, with the notable exception of ADH, which we directly compared (Partridge *et al.* 2006). ADH genes could be regulated differently or it could be due to experimental differences. The experimental design of Partridge *et al.* (2006) involved transitioning an anaerobic chemostat to aerobic conditions. It is possible trace alcohols were left over, and this caused an increase in ADH expression as a mechanism of uptake. Our *C. debilis* experiment was done in batch with aerobically grown inocula, and trace alcohols should not have been present under aerobic conditions. *C. debilis* produces acetate under aerobic conditions; the lack of significant change in the Zmag value of acetate kinase (-0.43) versus the moderate change in the z-score (-1.28) of the corresponding gene in *E. coli* K-12 corroborates this. Increased expression of PDH in *C. debilis* GB1 under aerobic conditions is consistent with the *E. coli* K-12 set for which we compared.

We expected an increase in genes associated with ROS under aerobic conditions to deal with oxidative stress. While facultative organisms typically express catalase in high amounts, as seen within our proteome, the magnitude of the change in expression was not statistically significant. Catalase was significantly up-regulated in in the Partridge *et al.* (2006) *E. coli* K-12 dataset. Overall the pooled $\log_2$(TIC) of gene products involved in ROS protection were consistent with the *E. coli* K-12 data set by Partridge *et al.* (2006) showing catalase is highly expressed.

Energy production and conversion is a core metabolic process in bacterial cells, and the ability to undergo respirative and fermentative metabolism is a key feature of energy production (Nakano *et al.* 1998, Partridge *et al* 2006). While each organism may have unique features with respect to gene content, expression, and physiology as a whole, many facultative anaerobes share expression patterns at the pathway level. To demonstrate this, we created a correlation plot of the average Zmag values of *C. debilis* GB1 proteins in the key catabolic pathways under aerobic versus anaerobic conditions to the average Z-scores of *E.coli* K-12 gene transcript profiles, from equivalent pathways, under aerobic and anaerobic conditions using data generated by Partridge et al. (2006).

A correlation plot (Figure 4.8) between *C. debilis* GB1 and the data set from *E. coli* K-12, from Partridge *et al.* (2006), show average changes (Zmag values in *C. debilis*, z-score in *E. coli* K-12) between anaerobic and aerobic conditions for the core catabolic pathways discussed in the sections above, with a high R^2 value of 0.54. When genes are plotted individually (Figure 4.9) a similar relationship is observed with correlation between expression changes in *C. debilis* GB1 and *E. coli* K-12

showing a R^2 of 0.41, confirming the validity of the use of pathway averages in Figure 4.8.

Each pathway appears to follow the same pattern of up regulation and down regulation in both *E. coli* K-12 and *C. debilis* GB1.We have included two notable exceptions: i) ADH's appear to be regulated oppositely, likely due to trace ethanol being present under the *E.coli* K-12 growth and sampling conditions as discussed above; and ii) the Cellobiose ABC transporters, as the IIB-cellobiose specific component is depressed (Zmag -3.7) in GB1 but not in *E.coli* K-12 (z-score 0.05) aerobically. A discordance between cellobiose ABC transporters is not surprising since they were grown using two related, but different, substrates (glucose for *E. coli* K-12 and cellobiose for *C. debilis* GB1).

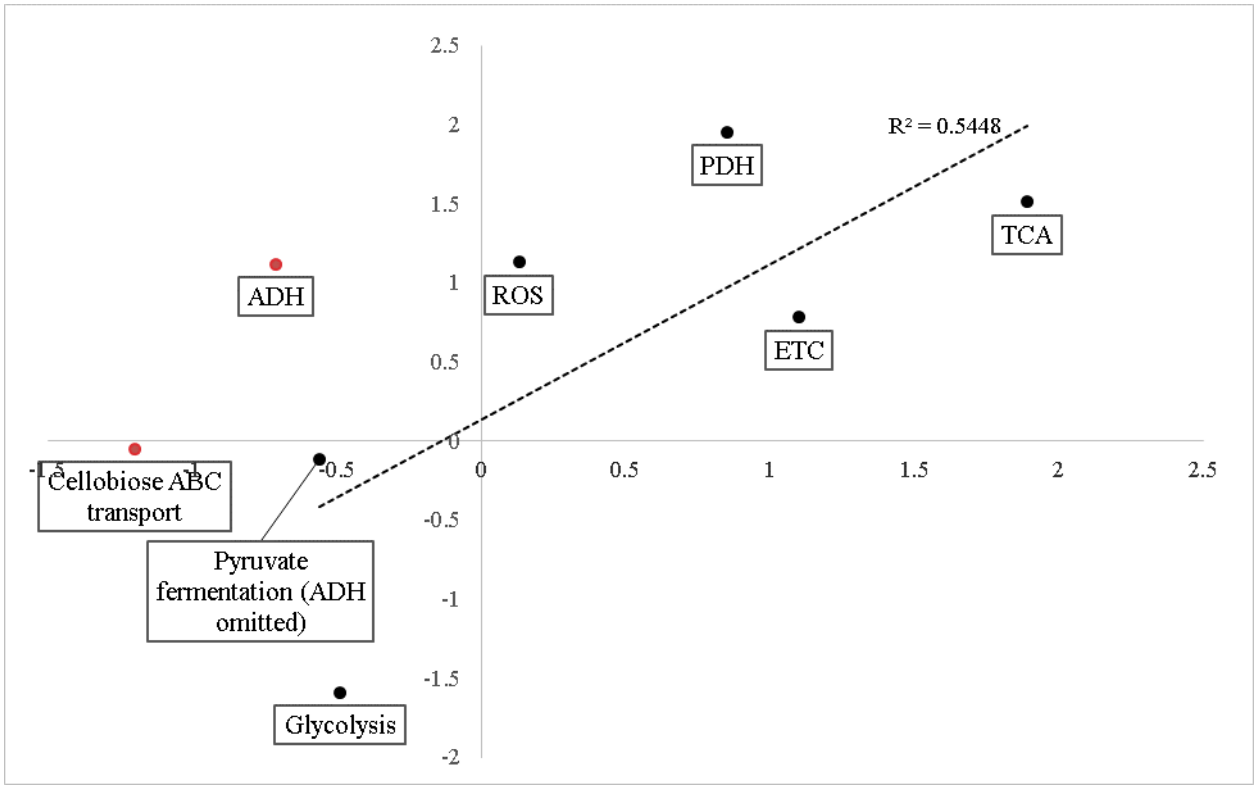

Figure 4.8. Average Zmag (x-axis) values and Z-scores (y-axis) comparing anaerobic to aerobic conditions of *C. debilis* (x-axis) and *E. coli* K-12 (y-axis) core metabolic pathways (listed in Table 4.2). Dots in red indicate gene expression changes that are discordant

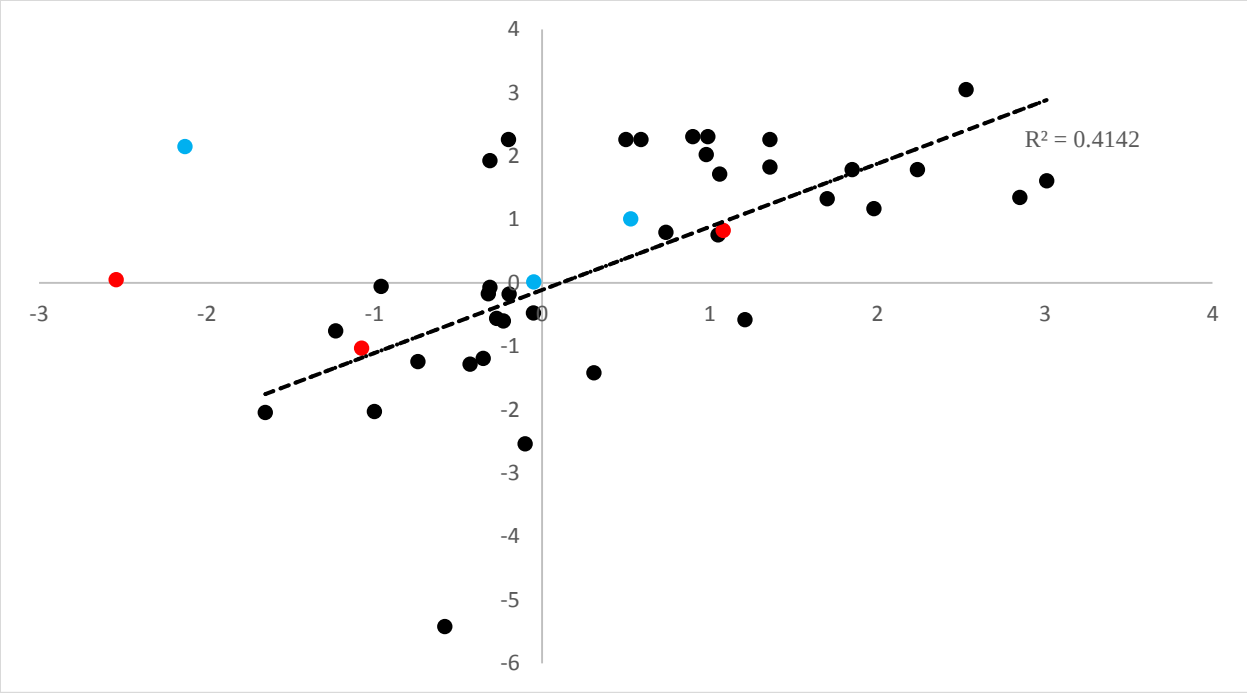

Figure 4.9. Zmag (x-axis) values and Z-scores (y-axis) comparing anaerobic to aerobic conditions of *C. debilis* (x-axis) and *E. coli* K-12 (y-axis) core metabolic pathways (listed in Table 4.3). Dots in black represent ETC, ROS, TCA, PDH, pyruvate fermentation (ADH omitted), and glycolysis. Dots in red (cellobiose ABC transport) and blue (ADH) indicate gene expressing changes that are discordant. R2 displayed in chart is for the black dots.

When we consider core metabolic regulation in response to aerobic and anaerobic conditions of the facultative anaerobe, *B. cereus* (Van Der *et al.* 2009), and studies on the regulation of *E. coli* K-12 (Partridge *et al.* 2006, Weber *et al.* 2006), the regulation pattern is rather similar in that increases in TCA, ETC, PDH expression under aerobic conditions and a decrease in glycolysis and fermentation associated genes are observed. Our data compared by our proteomic/transcriptomic methods closely matches observations made by others using various functional genomic methods (Partridge *et al.* 2006, Van Der Voort *et al.* 2009).

4.5. Conclusion

Our goal was to understand *C. debilis* central metabolism in regards to aerobic and anaerobic growth using high throughput techniques to give us insight into the inner workings of core metabolism in *C. debilis*. Comparing against *E. coli* K-12, a mesophilic Proteobacteria, allowed us to understand *C. debilis*, a thermophilic *Firmicute*, core metabolism in a broader context. We quantified the changes in protein expression levels using 2D –LC-MS-MS in *C. debilis* GB1 under aerobic versus anaerobic conditions. Although some variability between biological replicate samples was observed, the trends established by quantitative and statistical analyses revealed significant changes in many metabolic pathway gene products under aerobic versus anaerobic conditions. Even in pathways that did not show many proteins with a significant change in expression (Zmag= ±1.65, representing a 3.2 fold change in expression) at the level of the individual proteins, the average Zmag values across pathways showed general trends that would be expected in changes from aerobic to

anaerobic metabolism. We further compared changes in protein expression levels in *C. debilis* GB1 to changes in gene (transcription) expression levels observed in *E. coli* K-12 under similar conditions, and found very similar changes at the pathway level, as well as at the level of specific genes and gene products that one would not expect to be correlated. These data would indicate that there are common, global regulatory changes in diverse facultative bacteria: Gram positive (Firmicutes) versus Gram negative (Proteobacteria); mesophilic versus thermophilic. There are many studies comparing different organisms using omics to compare closely related strains or species (Lidbury *et al.* 2016, Goltsman *et al.* 2009). Comparing and understanding how novel and different organisms act in relation to well-studied organisms such as *E. coli* is important. Many of the gene annotation and gene functions have been tested in *E. coli*, therefore one can have greater confidence in understanding the data in *E.coli* compared to most other organisms. This study sought to understand anaerobic and aerobic regulation in *C. debilis* GB1 and this information is better understood in the context of the well-studied model organisms such as *E. coli*.

Chapter 5: Genomic Comparison of Facultatively Anaerobic and Obligately Aerobic *Caldibacillus debilis* Strains GB1 and Tf Helps Explain Physiological Differences[4]

5.1. Abstract

Caldibacillus debilis strains GB1 and Tf display distinct phenotypes. *C. debilis* GB1 is capable of anaerobic growth, and can synthesize ethanol while *C. debilis* Tf cannot. To help provide insights on these physiological differences, the genome of strain GB1 was sequenced. Comparison of the GB1 and Tf genome sequences revealed that the genomes were highly similar in gene content and showed a high level of synteny. At the genome scale, there were several large sections of DNA that appeared to be from lateral gene transfer to the GB1 genome, including: several cryptic prophage regions both internal and at contig ends, ~223,088bp of conjugation equipment, and a ~5kb plasmid. Tf did have unique genetic content but at a much smaller scale, 300 genes in Tf verses 857 genes in GB1 that matched at ≤90% sequence similarity. Gene complement and copy number of genes for the glycolysis, tricarboxylic acid (TCA) cycle, and electron transport chain (ETC) pathways were identical in both Tf and GB1. In addition, branched fermentation pathway genes were

present in both strains, suggesting that both contain the gene complement necessary for both aerobic and anaerobic growth. Indeed, while Tf is an obligate aerobe, it possesses the gene complement for an anaerobic life style (*ldh, ak, pta, adhE, pfl*). There are only several minor genetic differences observed in regions of some key genes that may help explain some of the physiological differences (e.g. minor differences in *adhE* sequence between the strains). However, genomic comparisons did not reveal direct evidence explaining why strain Tf is not capable of growth in the complete absence of oxygen. This suggests that, as a species, *C. debilis* other strains should be expected to have the potential for anaerobic growth.

5.2. Introduction

Caldibacillus debilis GB1 was isolated from a co-culture found to convey aerotolerance to *C. thermocellum* when co-cultured aerobically on cellulose (Chapter 2). The recently defined, single species genus *Caldibacillus* has been the subject of only a few physiological studies in pure culture (Banat *et al.* 2004; Chapter 3). One major difference between these strains is the ability of strain GB1 (but not the type strain Tf) to grow anaerobically and synthesize ethanol under the conditions tested. *Caldibacillus debilis* Tf was also unable to create a micro-aerophilic environment suitable for co-culturing with the strict anaerobe *C. thermocellum*, contrary to what was observed with *C. debilis* GB1 (Chapter 3). We believe that the inability of Tf to grow anaerobically, or at low O_2 concentrations may affect its ability to create the reduced anaerobic microenvironment needed for *C. thermocellum* to thrive.

Previously, Wushke *et al.* (Chapter 3) compared the physiological profile of two strains of *C. debilis*, GB1 and Tf. They showed near identical characteristics in growth rate, temperature optimum, substrate utilization profile, and types of end-products produced under aerobic and oxygen-limiting conditions (with the notable exception of ethanol production). A *C. debilis* Tf draft genome has been generated and annotated by the Joint Genome Institute (JGI) (Grigoriev *et al.* 2012), but there has not been a detailed genome analysis published. The *Caldibacillus debilis* GB1 genome was previously sequenced and its proteome was analyzed with respect to aerobic and anaerobic growth (Chapter 4). Due to several major physiological differences, including anaerobic growth and ethanol synthesis, we hypothesized that a comparison of the genomes of the GB1 and Tf genome sequences, with a focus on core metabolism, could explain the observed physiological differences.

5.3. Materials and Methods

5.3.1. Cell Culturing

The methods for *Caldibacillus debilis* strain GB1 DSM 29516 and *C. debilis* Tf DSM 16016 cultures were described previously (Chapter 2 and 3). *C. debilis* strains were grown on modified 1191 (M-1191) medium (Islam *et al.* 2006) with a lower concentration of yeast extract (0.76 g/L) and the pH was adjusted to 7.2, for all experiments. Sealed Balch tubes (26 mL) from Bellco Glass Inc. (Vineland, NJ) and 1L Corning bottles supplied from Fisher Scientific (Toronto, ON), were used to carry

out experiments. Anaerobic and aerobic environments in Balch tubes and Corning bottles were prepared as previously described by Wushke *et al.* (Chapter 3).

5.3.2. Genomic Comparison

The GB1 genome was sequenced and annotated as previously described (Chapter 4). The GB1 and Tf genome sequences can both be accessed through the National Center for Biotechnology Information (NCBI) under the catalogue numbers AZRV00000000 and ARVR00000000, respectively. Joint Genome Institute (JGI) Integrated Microbial Genomes (IMG) Expert Review (IMG/ER) was used to compare the bacterial genomes (Markowitz *et al*. 2008). NUCmer plots were generated through IMG/ER. Gview was used to create genome-scale comparative images (Petkau *et al.* 2010). Protein and DNA alignments were done with Multiple Sequence Alignment Tool (MUSCLE) (Edgar *et al.* 2004). NCBI Blast was used create a 2D model of domains and key amino acids involved in function (Johnson *et al*. 2008). 3D models of the ADHE proteins were created using RAPTORX (Källberg et al. 2012).

5.3.3. Protein Extraction

Samples for protein extraction were collected during early exponential in aerobic growth shaken at 150rpm for both strains GB1 and Tf. Approximately ~200 mg cell pellets were washed twice in phosphate buffered saline (PBS) buffer then re-suspended in 1 mL of lysis buffer [1% sodium dodecyl sulfate (SDS), 100 mM dithiothreitol (DTT)] in 100 mM ammonium bicarbonate (ABC)). The mixture was

vortexed for 30 seconds (sec), then placed in boiling water for 5 minutes (min), and then cooled for 5 min. Samples were then sonicated three times with 15 sec pulses, and 1 min breaks in-between then were centrifuged at 16000 x g for 20 min. Supernatants containing the proteins were kept for further processing, and stored at -80 ºC. Aliquots (20 µL) of the protein containing supernatants were diluted with 180 µL of 100 mM ABC buffer. Twenty (20) µL of 500 mM iodoacetic acid (IAA) were added, vortexed for 5 sec and stored in the dark for 45 min to complete alkylation. To quench excess IAA, 33 µL of 100mM DTT was added. Then, 150 µL of ABC were added to bring total volume to ~380 µL to reduce the SDS concentration in order to allow digestion. Trypsin (4 µg) was added, and $CaCl_2$ was added to a final concentration of 10 mM. Samples were incubated for 12 hours at 37 ºC to allow trypsinization to occur. Samples were then dried using roto-evaporation (Savant Speedvac-sc110), and 200 µL of 3 M KCl was added and vortexed for 10 min, then were spun at 16000 x g for 25 min and supernatants were gently removed from the precipitate (containing the SDS, which is incompatible mass spectrometry methods). The samples were diluted 2 fold with 0.5% trifluoroacetic acid (TFA) then desalted by HPLC using a C18 column as described previously (Chapter 4).

5.3.4. Mass Spectrometry Methods

One-dimensional liquid chromatography followed by mass spectrometry (1D-LC-MS) proteomics were used to identify proteins by their peptide sequences, as previously described by Gungormusler-Yilmaz *et al.* (2014). Proteomic profiles of the

C. debilis strains GB1 and Tf grown to early exponential phase on cellobiose were compared using an in-house data analysis system called UNITY, as previously described (Fu *et al.* 2015) was used. The XML output file from an X!tandem search and its corresponding TIC intensity's can be found at http://hs2.proteome.ca/thegpmcgi/plist.pl?path=/gpm/archive/C.debilis_GB1/GB1A-BASERESULTS.xml&proex=-1&npep=0 and http://hs2.proteome.ca/thegpm-cgi/plist.pl?path=/gpm/archive/C.debilis_GB1/GB1B-BASERESULTS.xml&proex=-1&npep=0 and http://hs2.proteome.ca/thegpm-cgi/plist.pl?path=/gpm/archive/C.debilis_GB1/DSM1606AX-BASERESULTS.xml&proex=-1&npep=0.

5.3.5. Proteogenomics

To enhance the genome sequence and annotation, a proteogenomic approach was used. We have described, previously, the use of proteomic data to identify and correct improperly annotated genes using a naïve assembler (Chapter 4) using the same methodology as Verbeke *et al.* (2014). In this study two proteomes were generated, one for each, GB1 and Tf, during early exponential under aerobic conditions on cellobiose. We used these proteomic data to verify unique regions and genes missing in the *C. debilis* GB1 and Tf genome by analyzing each strains proteome with respect to both the GB1 and Tf genomes.

5.4. Results and Discussion

5.4.1. GB1 and Tf Genome Comparison

A summary of the GB1 and Tf genomes containing 49 and 41 contigs respectively can be found in Table 5.1. The genome sequences of *C. debilis* strains GB1 and Tf are highly similar in both gene identity and genome synteny (2354 genes in matching cassettes, where a cassette consists of blocks of associated genes in sets of 2 or more). GB1 has 2570 genes matching Tf with a sequence identity ≥90%. Figure 5.1 shows a NUCmer plot demonstrating their synteny produced using IMG/ER. When the genome sequences of the two strains were compared, there were 853 genes in GB1 that did not match with a sequence identity greater than or equal to 90% in Tf. Since these strains primarily have highly related genes, matches with ≤90% sequence identity were considered to be unique. The majority of unmatched genes found in GB1 were hypothetical (408). Many of the unmatched genes could be attributed to three structural differences: i) the addition of 207 genes on contig 4, which appear to form a conjugative element; ii) the addition of a full length genome of a cryptic prophage genome on contig 16, as well as several partial copies associated with the end of various contigs, and iii) a phage-related circular plasmid found as contig 31. There were also 16 transposase associated genes dispersed through the genome. Figure 5.2 shows a graphical representation of the GB1 and Tf unique genomes with genes matching at ≤90% sequence similarity produced by GView. In contrast to GB1, Tf has only 300 unique genes that do not match sequences in the GB1 genome at a ≤90% sequence similarity.

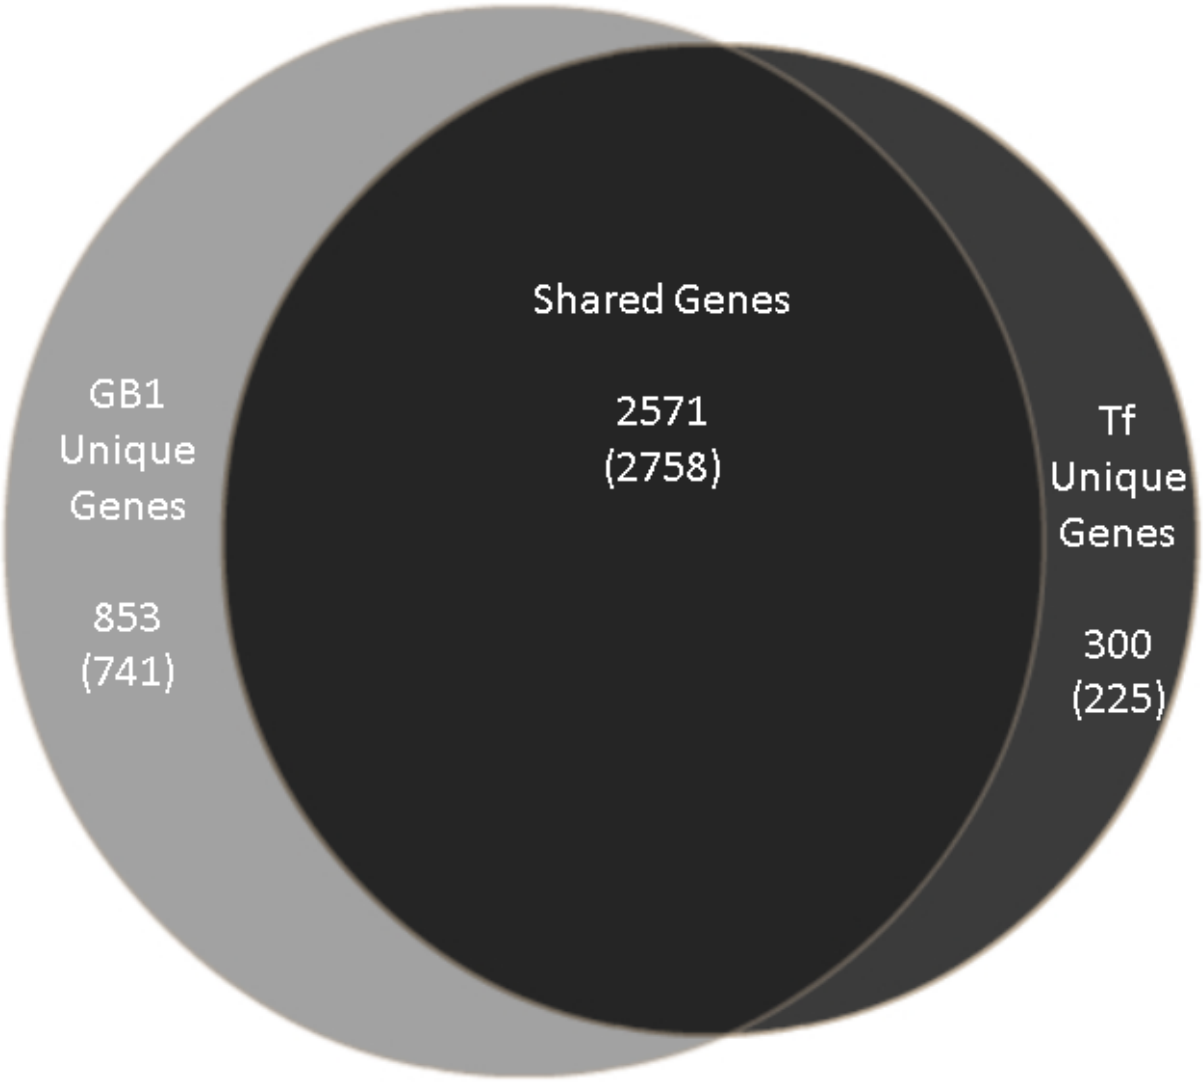

Figure 5.3. Venn diagram of genes unique to *C. debilis* strains at a ≤90% sequence similarity cut off. Brackets "()" refer to the number of genes shared when a ≤60% sequence similarity cut off is used.

Differences in tRNA complement have the potential to affect gene regulation at a global level. Sequence analyses of GB1 revealed that there are 25 tRNA genes on contig 4 that are associated with the conjugative element described above. Thanks in part to this addition, there are 85 tRNA genes in GB1 compared to only 58 in Tf, as shown in Table 5.2. All of the tRNA's unique to GB1 had anticodons that were shared by Tf and GB1, therefore the codon usage ability was not expanded. A change among tRNA availability could have an effect on translation regulation. The tRNA did not appear to be the cause of differences in anaerobic ability between the strains, as the added tRNA's did not appear to change the codons used.

5.4.2. Proteogenomics

The general features of the *C. debilis* GB1 genome have been described previously, and proteogenomics used to correct annotation start sites (Chapter 4). In this study we used a further single proteome for each strain, GB1 and Tf, during early aerobic growth (sampling point is shown in Figure 5.4) in order to: i) check for genes that were missed due to incomplete sequencing and/or annotation; and ii) check whether or not genes in regions which appeared unique to GB1 were expressed. Depth of coverage, however, was rather poor, with 704 and 473 proteins detected for GB1 and Tf respectively. Nevertheless, when the proteome of strain Tf was compared against the GB1 genome, 1 gene, LSU ribosomal protein L36P (Cdeb_03413), had peptide signals that had not been observed when the Tf genome analysed with the Tf proteome. Tf possessed the exact same DNA sequence but was partially overlapped by another gene. The lack of an ORF for this gene in Tf genome is likely due to a difference in the annotation methods used due to preference of an overlapping ORF. The GB1 proteome did not display any additionally detected proteins when analyzed against the Tf genome, suggesting its genome sequencing was more complete than the Tf genome sequence. The regions that appeared to be unique to GB1, a cryptic prophage region within contig 16 and conjugation equipment comprising contig 4, resulted in 5 and 3 proteins detected respectively. When the Tf proteome was used to check for GB1 genes in the regions that appeared to be from a lateral gene transfer, no proteins were found corresponding to these genes suggesting that the DNA which appears to be exogenously introduced into GB1 through lateral gene transfer is likely unique to GB1.

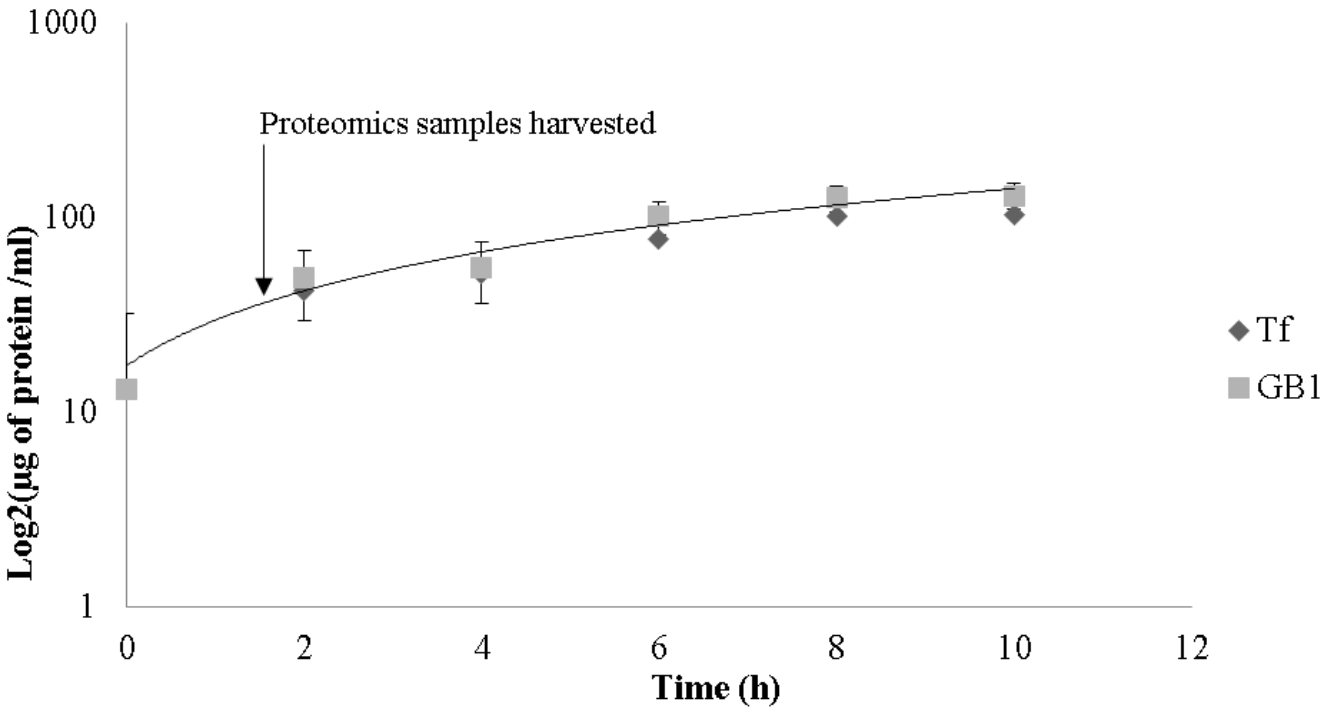

Figure 5.4. Growth curve and sampling point of *C. debilis* Tf and GB1 used for proteomics

5.4.3. Core Metabolic Genes Relative to Observed Phenotype

The primary reason for the present comparative study was to understand the significant differences in end-product synthesis profiles between the two strains. While both strains were able to produce lactate, acetate, formate, and CO_2 under oxygen-limiting conditions, the Tf strain lacked ethanol production under oxygen-limiting conditions, and showed an inability to grow anaerobically (Chapter 3). GB1, under oxygen-limiting conditions, showed the ability to produce ethanol and grow aerobically. Focusing on the genes responsible for core catabolic activity, the gene complement in strains GB1 and Tf were found to be identical and the genes appeared in similar genetic contexts in both genomes.

An overview of core metabolism in *C. debilis* GB1 can be found in our previous work Wushke *et al.* (Chapter 4). When the gene complement needed for pyruvate fermentation is considered, GB1 and Tf have the exact same complement and number of genes. A list of GB1 core metabolic genes and the corresponding locus tags for Tf can be found in Table 5.3. The differences between GB1 and Tf are in bold the pyruvate kinase (Cdeb_02915, Cdeb_02914) which was annotated as separate but adjacent genes with different annotated functions in GB1 and one gene, a pyruvate kinase, in Tf even though DNA in the coding region is 100% identical.

Table 5.3. Core metabolism locus tags of GB1 and Tf that matched with ≥90% identity, and predicted function as specified through KEGG maps built in IMG/ER

Differences in annotated genes are show in **Bold**; [a]pyruvate kinase gene was split in GB1 and the adjacent ORF's were given different annotated functions.

5.4.4. Pyruvate Fermentation

When focusing on pyruvate fermentation pathways, small differences were observed in regions within 200bp up stream of a number of genes of interest shown in Figure 5.5: *adh* (Cdeb_03022, Cdeb_00489, Cdeb_01569, Cdeb_01590), *aldh*(Cdeb_00412, Cdeb_02563), *adhe* (Cdeb_01397), *ak* (Cdeb_03124), *pta* (Cdeb_00469), *pfl* (Cdeb_01637/01638) and *ldh* (Cdeb_02710). When examining the genes each appeared to have a putitive TATAAT box and transcription start site. Nevertheless, in some cases, the differences in the upstream regions between GB1 and Tf were extensive (*adh*), compared to others (*ak*, *pta*, *adhE*, *aldh*) as seen in Figure 5.5. Figure 5.6 shows the amino acid sequence alignments of genes in pyruvate fermentation that are not perfect matchs. Figure 5.7 is the *adhE* DNA alignment. The activity of key enzymes PFL, LDH, AK, ADHE could be verified by end-product analysis under oxygen-limited conditions, as their corresponding products were detected, with the exception of ethanol in Tf, even though the genome of strain Tf encodes ADHE. ADHE is the primary enzyme responsible for ethanol synthesis in many anaerobes (Carere *et al.* 2012).

Interpreting changes at the nucleotide level in and surrounding the core metabolism genes must be approached with caution as differences are also consistent with what would be expected in distinct strains (Hayashi *et al.* 2001). Indeed many of the differences noted between GB1 and Tf would not be expected to affect gene expression or activity (*i.e*. silent mutations, mutations in non-coding areas).

Figure 5.6. Pyruvate fermentation enzyme protein alignments that do not match perfectly through MUSCLE alignment (ADH ADHE, AlDH, PFL) arranged alphabetically "*" indicate a matching amino acid; "." Indicate semi-conservative; ":" indicate conservative; Blank spaces " " indicate non conservative; non-matching AA are highlighted in red.

5.4.5. Lactate Dehydrogenase

Many wild type thermophilic and mesophilic organisms synthesize lactate as a major fermentative end-product (Narayanan *et al.* 2004). Both strains of *Caldibacillus debilis* produce very little lactate, with lactate production typically comprising less than ~10% of carbon end-products (Chapter 3). Indeed, lactate dehydrogenase is not highly represented in the *C. debilis* GB1 proteome (Chapter 4), nor in the present study. In either strain, it was near the limit of detection when detected. Therefore low lactate production is correlated with low LDH expression levels. Lactate production can also be regulated allosterically, therefore the presence of LDH does not guarantee production of lactate (Rydzak et al. 2009) While indeed lactic acid production was low in both organisms, we do see differences in lactic acid production between the strains as well, with GB1 typically producing significantly less than Tf under comparable conditions (Chapter 3). Clear genetic reasons for difference in lactic acid production were not apparent.

5.4.6. Pyruvate Dehydrogenase

PDH in general can be used aerobically or anaerobically (Nakano *et al.* 1997). PDH can be important under anaerobic conditions in pyruvate metabolism. Other work on the related *G. thermoglucosidasius* focused on changing the PDH promoters to allow for higher PDH production under anaerobic conditions (Cripps *et al.* 2009). In *C. debilis* GB1 anaerobic growth does not appear to utilize PDH, as CO_2 appears only in trace concentrations anaerobically (Chapter 3). Previous work, Wushke *et al.* (Chapter 4), suggests that PDH is down regulated

anaerobically. While both Tf and GB1 have a PDH that could be utilized anaerobically, it appears that regulation limits its usefulness anaerobically. The differences between strains Tf and GB1 appear to be due to genes concerning anaerobic growth. PDH appears to be unimportant in determining the ability for these organisms to grow anaerobically.

5.4.7. Pyruvate Formate Lyase

When cultured under oxygen-limiting conditions both strains, GB1 and Tf, synthesize formate and acetate as end-products (Chapter 3). There is a difference in formate production under oxygen-limited conditions; significant differences in the upstream regions of PFL are observed. Production of formate and acetate alone from pyruvate cannot act as an electron sink for NADH generated by glycolysis. Under conditions where oxygen is present, Tf is able to get rid of the excess electrons generated through glycolysis via the electron transport chain (ETC). If typical glycolysis and PFL are the primary means by which acetyl-CoA is generated, then anaerobic growth is not possible unless an additional reduced compound is produced. Strain GB1 is capable of anaerobic growth because it is also able to synthesize ethanol. Typically expression of an aero-sensitive enzyme, such as PFL, is linked to anaerobic metabolism (Nakano *et al.* 1998), and the use of PFL can be important for biosynthesis (Rydzak *et al.* 2015). More likely, Tf represents a strain that has lost the ability to produce ethanol, preventing anaerobic growth. Tf still maintains regulation and expression of PFL as we see formate production under oxygen limiting conditions only. Since both strains have the proper gene complement, and demonstrate the ability to utilize PFL, as indicated by the presences of formate, the focus should be on ethanol production genes, since this is where there is a clear physiological difference.

5.4.8. Alcohol Aldehyde Dehydrogenase

The synthesis of ethanol appears to be the main mechanism used by *C. debilis* GB1 to dump excess electrons from glycolysis under anaerobic conditions, as lactic acid production seems to be limited in some way in both strains under the growth conditions used (Chapter 3 and 4). Ethanol synthesis may therefore be an anaerobic requirement in *C. debilis* GB1. Strains GB1 and Tf are highly similar organisms based on the fermentation pathway profile at the genome level. Both strains of *C. debilis* have a single copy of *adhe* as well as 4 and 2 discrete copies of *adh* and *aldh* respectivly. The *adh* genes have not been characterised for there specificity and could be playing a role in other functions. ADHE is associated with the bulk of ethanol production in many anaerobic organisms (Carere *et al.* 2012, Peng *et al.* 2008). Indeed, in the closely related *G. thermoglucosidasius,* an ADHE deletion mutant eliminates ethanol production despite the presence of both *adh* and *aldh* in their genome (Extance *et al.* 2013).

The lack of ethanol synthesis in *C. debilis* Tf could be understood through looking at the sequence of the bifunctional alcohol/aldehyde dehydrogenase (*adhE*) gene. While the genomes of both strains encoded a putative ADHE enzyme, detailed analyses revealed sequence differences in regions upstream, as well as within the coding sequence of the *adhE* gene. Figure 5.08 shows the protein alignment of ADHE. Nucleotide substitutions in the ADHE coding sequence, shown in Figure 5.10, result in different amino acids: GB1 → Tf = 269A→E, 482D→E, 495V→I, 825D → A, 829R → K, 831P→H. These amino acid changes were caused by a single nucleotide polymorphism in all but one case, V→I where two bp were changed. Changes 482D→E and 495V→I, appear to be benign mutations resulting in amino acids with similar properties. Both codon changes, 825 D→A and 829R→K, are seen in other functional

ADHE alignments and seem to be normal variations in coding sequence (Extance *et al.* 2013). 269A→E appears to be a missense mutation rather close to a putative catalytic cysteine at position 255. The 831P→H codon change is a missense mutation that appears to place a charged amino acid in an α-helix region on the outer shell of the Tf ADHE protein. The changes in the ADH domain of ADHE are not within any putative active site, cofactor binding-site, or known allosteric regulation site (Zheng *et al.* 2015). These amino acid substitutions affect a small loop connecting an α-helix region (Extance *et al.* 2013), and therefore could affect overall protein or multimeric protein structure. Figure 5.11 is a 2D representation of ADHE with domains and key sites specified generated through NCBI BLAST. Figure 5.12 and 5.13 are 3D models created in raptorX of ADHE in GB1 and Tf. Figure 5.13 show the domain alignments and the structural differences caused by the amino acid differences at positions 269 and 831.

Differences in *adhE* gene expression regulation or ADHE enzyme activity could result in the ethanol-minus Tf phenotype and explain the lack of anaerobic growth. While there are also differences in regions upstream of *adhE*, they did not appear to affect the promoter binding site.

Geobacillus thermoglucosidasius is similar to *C. debilis* GB1 in that it has the same major end products, similar core metabolism gene complement encoding ADH, AlDH and ADHE, the ability to grow anaerobically, and is a closely related genus that previously included *C. debilis.* A study by Extance *et al.* (2013) noted that gene knock-outs of *G. thermoglucosidasius* ADHE results in a lack of anaerobic growth and an ethanol-minus phenotype, very similar to the Tf phenotype. Taken together the results imply the phenotype differences observed when comparing GB1 and Tf are likely due to the differences in the amino acid sequence of the ADHE.

CLUSTAL multiple sequence alignment by MUSCLE of *adhE* coding DNA

5.4.9. Cellobiose Phosphotransferase Systems

Other differences of note between GB1 and Tf include the apparent differences in the gene complement of the Phosphotransferase (PT) systems, especially concerning PT systems with putative cellobiose specificity (Table 5.4). This is not surprising, due to the fact that strain GB1 was enriched and purified under conditions containing cellobiose (Chapter 2), while strain Tf was not (Banat *et al.* 2004). Furthermore *C. debilis* GB1 was isolated from a cellulolytic aerotolerant enrichment containing *C. thermocellum* to which it provided aerotolerance. Under enrichment conditions *C. debilis* GB1 and *C. thermocellum* would likely compete to get sugar resources.

5.4.10. Respirofermentative Metabolism

Figure 5.11 displays the core pathways involved in growth of Tf under low concentrations of oxygen. Previous experiments done by Wushke *et al.* (Chapter 3) characterised end-product production on cellobiose aerobically and anaerobically for strains GB1 and Tf. Under conditions where oxygen concentrations are low Tf and GB1 both utilise respiration and fermentation, also called respirofermentative growth (Siso *et al.* 1996). During respirofermentative growth, fermentation products are produced, and the excess electrons from metabolism can then be used through the ECT to create ATP or used to create a reduced end-product. GB1 can either use its excess electrons to create ethanol and/or lactate and/or use them in ECT, based on end-product production under oxygen limiting conditions it appears to do all three. Tf when undergoing respirofermentative growth utilizes the ETC and produces lactate as the only reduced end-product. Tf fails to grow under anaerobic conditions most likely due to an inability to produce ethanol. While Tf could balance its electrons anaerobically by producing lactate alone, Tf does not do this. While Tf and GB1 both have additional discrete *adh* and *aldh* genes, they may not be involved in alcohol synthesis, Wushke *et al.* (Chapter 3) show GB1 is capable of consuming ethanol aerobically.

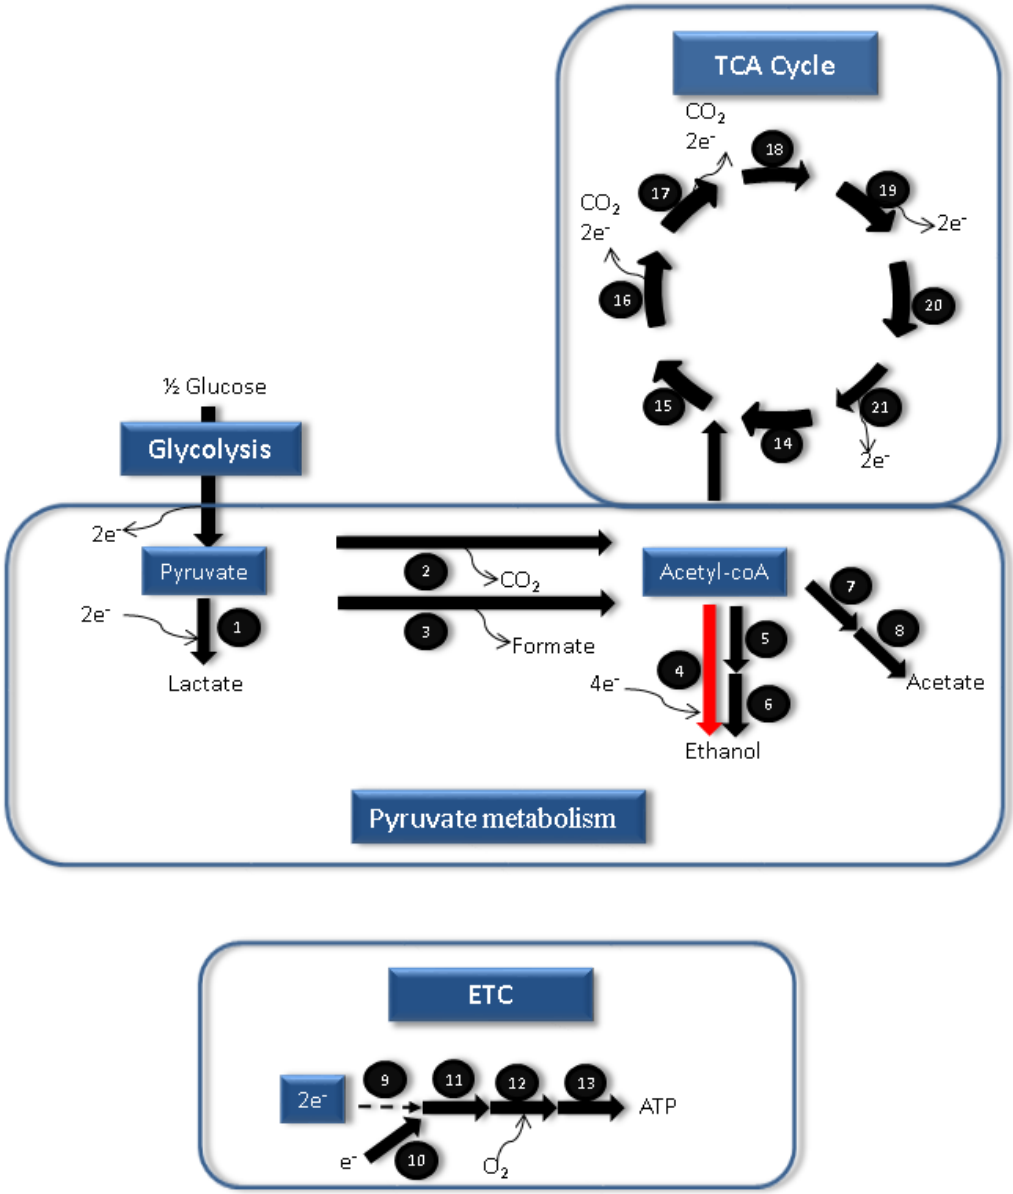

Figure 5.11. Respirofermentive metabolism *C. debilis* strains GB1 and Tf. enzymes 1) lactate dehydrogenase (LDH); 2) pyruvate dehydrogenase (PDH); 3) pyruvate formate lyase (PFL); 4) alcohol/aldehyde dehydrogenase (ADHE); 5) aldehyde dehydrogenase(ALDH); 6) alcohol dehydrogenase(ADH);7) phosphotransacetylase (PTA); 8) acetate kinase (AK); 9) complex I; 10) complex II; 11) complex III; 12) complex IV; 13) ATP synthase/complex; 14) citrate synthase; 15) aconitate hydratase; 16) isocitrate dehydrogenase; 17) alpha-ketogultarate dehydrogenase; 18) succinyl-CoA synthase; 19) succinate dehydrogenase; 21) fumerate hydratase; 22) malate dehydrogenase

5.5. Conclusion

No direct evidence was found to explain the lack of anaerobic metabolism and lack of ethanol production phenotypic differences by superficial examination of the overall annotated genome content and organization. However, closer examination of the gene sequences revealed evidence of differences within specific genes pertinent to anaerobic metabolism that could affect enzymatic activity. Tf is unable to produce ethanol under conditions where oxygen is limiting. The inability of Tf to produce ethanol is the likely cause of the lack of anaerobic growth phenotype. As ethanol production is typically produced through the ADHE enzyme in related genera, it is likely that the lack of ethanol production is caused by a defective *adhE* gene. (Extance *et al.* 2013). Indeed, the Tf strain phenotype closely matched an ADHE knockout phenotype in a related species, *G. thermoglucosidasius,* giving further credence to the hypothesis that ADHE expression or functionality is different in strain Tf. Differences in ADHE activity or expression is a plausible scenario leading to the observed phenotypic differences between Tf and GB1.The argument for differences in the ADHE activity is strengthened through observed amino acid changes in the ADHE seen in genome analysis.

Overall *C. debilis* GB1 and Tf are very similar organisms at the genetic level, in both synteny and gene complement, including core metabolism pathway genes. Through our genome analysis a gene complement consistent with fermentation (*pfl, ldh, ak, pta,* and *adhE*) was observed in Tf and GB1. Tf likely evolved from a strain that could ferment cellobiose. The ability of *C. debilis* GB1 to grow under anaerobic conditions and synthesize ethanol clearly distinguishes it from *C. debilis* Tf. The

genus description of strain GB1 should be amended to include anaerobic growth as a characteristic.

Chapter 6: General Discussion and Conclusions

6.1. Core Objectives

With the goals of reducing or slowing man-made climate change, and creating a sustainable economy/environment in mind, we must look at the obvious option of using non-fossil fuels to create a closed-carbon-loop in order to reduce GHG emissions (DeCicco *et al.* 2013). Converting lignocellulosic substrates into ethanol or hydrogen using Consolidated Bioprocessing (CBP) as a way of reducing carbon emissions is enticing. As this process is not currently cost competitive (Lynd *et al.* 2005, Olsen *et al.* 2012, Jouzani *et al.* 2015), and the optimal conditions and organisms for CBP have not yet been determined, discovering new organisms and expanding the operational parameters of CBP is essential to developing an optimal process.

With the goal of discovering a suitable organism for CBP, or one able to act synergistically with those currently used, in mind, we address our contributions through the objectives below:

Objective 1: Find and describe aerotolerant cellulolytic fermentative consortia.

A wide variety of environments on a Saskatchewan farm were sampled, and several highly cellulolytic enrichments that possessed aerotolerance traits that could expand the mode of operation of CBP were created. Several stable, transferable, and plateable cultures that exhibited high cellulose degradation and aerotolerance for further processing were generated. As a method, creating enrichments that exhibit a

specific set of community phenotypes, such as aerotolerant lignocellulolytic fermentation, is not novel in and of itself, and has been described in past literature (Miyazaki *et al.* 2008, and Ronan *et al.* 2013). However as the source inoculum and exact environmental conditions vary from one sampling site to another, it can yield novel organisms and enrichments that provide a starting point to isolating novel bacteria and/or novel strains. We generated the B4-1 enrichment, which showed cellulolytic abilities, aerotolerance, and better ethanol total-yield production then other comparable enrichments.

Objective 2: Determine the minimum consortium with the phenotype of interest and characterize its novel component(s)

We used the organism composition from B4-1 to create a designer culture showing the same ability as B4-1. Characterisation of the enrichment showed that this culture likely consisted of just two organisms related to *C. thermocellum* and *C. debilis.* An isolate of *C. debilis* GB1 from B4-1 was added to *C. thermocellum* DSMZ 1237 to create a co-culture. Chapter 3 definitively demonstrates that *C. debilis* GB1 alone is able to lend aerotolerance to *C. thermocellum* DSMZ 1237 and create an aerotolerant, highly cellulolytic co-culture. An aerobically fermentative co-culture containing *C. thermocellum* is a novel mode of operation for CBP.

Isolation and characterisation of *C. debilis* GB1 showed it was quite similar physiologically to type strain with the exception of exhibiting the ability to grow anaerobically and produce ethanol. The type strain, *C. debilis* Tf, however, could not replace the isolate in co-culture with *C. thermocellum.* It was not able to generate a microenvironment suitable for the growth of *C. thermocellum.*

Objective 3: Characterize *C. debilis* GB1 novel components using genomics and proteomics.

At the time of isolation a genome for *C. debilis* was not available. We sequenced *C. debilis* GB1 and annotated its genome. We were specifically interested in aerobic and anaerobic growth of GB1 and understanding GB1 aerobic/anaerobic expression in pure culture to shed light on the interactions of the *C. debilis* GB1 and *C. thermocellum* designer co-culture. The *C. debilis* GB1 proteome was characterized under aerobic and anaerobic conditions. Protein expression was found to change at the pathway level and was consistent with what one would expect in mesophilic facultative anaerobic organisms such as *E. coli* or *B. cereus* with similar core metabolism gene complements (chapter 4). Further examples of direct omic comparisons between such distantly related organisms within the literature as *C. debilis* and *E. coli* could not be found. Omic comparisons have been mainly performed among similar species or strains (Lidbury *et al.* 2016, Goltsman *et al.* 2009). The comparison of a novel organism to a distant, but well studied, organism from a different phylum shows that it is beneficial in understanding expression at the omics level.

The proteomic information for genes which were detected and measured corroborates physiology concerning central metabolism. As cross-state proteomes using high throughput techniques on thermophilic *Bacillaceae* is rare in current literature, the description of the aerobic and anaerobic metabolism of *C. debilis* GB1 contributed directly to our goal of understanding the role of GB1 in our cellulolytic aerotolerant designer co-culture.

Objective 4: Characterization of GB1 against the type strain at the genomic level

The *C. debilis* GB1 genome was sequenced, annotated, and compared directly to the type strain Tf. Comparing and contrasting these organisms allowed for a better understanding of the features in *C. debilis* GB1 which make it a good co-culture partner for CBP, while the type strain could not. Tf was not able to recreate the same aerotolerant cellulolytic co-culture when mixed with *C. thermocellum* as GB1 could. Understanding why Tf was limited to aerobic growth and did not synthesize ethanol is core in understanding why it could not protect *C. thermocellum* from oxygen. This contributed directly to the goals of understanding physiology through the lens of genomics and proteomics using the omics techniques to corroborate the results of the other.

6.2. Thesis Work in the Context of 2016

Pure culture work is a core aspect of CBP and being able to understand and optimise a single organism is objectively easier than understanding and optimizing organisms in a co-culture. For the study of co-cultures, it is possible to take a reductionist approach, and analyze each organism individually or to study them as a co-culture. Our experiments built on studying an enrichment, B4-1, which had the property of being aerotolerant and highly cellulolytic.

Large amounts of work has been put into studying *C. thermocellum,* it is beneficial that our designer co-culture worked with the well characterized strain of *C. thermocellum* (DSMZ 1237). *C. thermocellum* was the main driver of cellulose

degradation in these cultures as *C. debilis* was not cellulolytic. *C. debilis* had previously not been well characterized, therefore extensive work characterising this organism at the physiological level and omics level especially concerning core metabolism and aerobic/anaerobic growth was performed. *Geobacillus* and the closely related *Caldibacillus* appear to be naturally occurring co-culture partners with *C. thermocellum* as they are frequently found together in enrichments (Ronan *et al.* 2013, Miyazaki *et al.* 2008). Interestingly, deliberate co-cultures containing *C. thermocellum* and organisms related to *Geobacillus* for the purposes of CBP are relatively rare in the literature (Lu *et al.* 2013). Characterisation of *Geobacillus* and/or *Caldibacillus* in the context of CBP is relatively sparse even though they appear to have very attractive abilities and can be readily optimized (Cripps *et al.* 2009). Other organism such as *Thermoanaerobacter sp.* appear to be favored as co-culture partners for *C. thermocellum*, perhaps due to their capacity for robust growth. Indeed several strains of *C. thermocellum* were shown to be co-cultures (Freier *et al.* 1988). In deliberate co-cultures *Thermoanaerobacter sp.* can have the aptitude for increasing ethanol or hydrogen yields (Fang 2010). *Thermoanaerobacter sp.*may also be useful in co-culture with *C. thermocellum* because of their ability to hydrolyse some components of lignocellulosic substrates as they can be highly xylanolytic (Verbeke *et al.* 2013). They are also capable of fermenting xylose, a trait the *C. thermocellum* does not have. Some members of the *Geobacillus*, and more closely related genera, have similar abilities (Brumm *et al.* 2015, Cripps *et al.* 2009). *Geobacillus* related organisms also appear to have some of the highest innate ethanol tolerance of thermophiles (Fong *et al.* 2006) and the ability to lend aerotolerance to strict

anaerobes as alluded to by others (Zuroff *et al.* 2013) and demonstrated decisively through our work.

In the context of 2016, designer co-cultures appear to be a highly researched mechanism to improving CBP (Jouzani *et al.* 2015). In many cases, it tends to have a positive effect when compared to corresponding pure cultures. However, as the future is difficult to predict it is unclear what combination of organisms, and what mode an economically viable CBP process will take.

6.3. Future Work

A comprehensive omics analysis of the co-culture of *C. debilis* GB1 and *C. thermocellum* in a steady state is the next step in this project. There is a large amount of omics information on *C. thermocellum* in pure culture, and we have built up omics information on *C. debilis* GB1 in pure culture namely genomic and proteomic through our work. We could leverage the pure culture information in comparison to that from the co-culture to understand the interactions between its members. This would give us essential information on how these organisms work together. We attempted to harvest samples for omics from co-cultures grown using pH controlled fermenters but only achieved mitigated success (see Appendix E for likely causes). Collecting omics data on CBP co-cultures in a co-cultured state to determine co-culture interactions is the next step and logical final goal for this project.

6.4. Conclusion

This designed co-culture was built on previous bioprospecting work. While genetic modification tools are becoming incredibly powerful, it is important to build those genetic modifications on an organism that is suitable. In choosing an organism to genetically modify to be a high ethanol producer why not use an organism that is already ethanol tolerant? Theoretically it may be possible to build a highly cellulolytic, high ethanol producing organism from the ground up, but this may not be the easiest path. One could instead find an organism that already has a majority of desired features.

C. debilis GB1 appeared distinct from the type strain Tf with the former being reported, and confirmed through our work, as a strict aerobe. In side-by-side comparison with strain GB1, we have confirmed that Tf cannot grow in media that permit anaerobic growth of strain GB1. Our work here elucidates the anaerobic metabolism in *Caldibacillus* and that the strain Tf, while appearing to have the gene complement for ethanol and anaerobic metabolism, is limited due to difference in ADHE functionality. The characterisation of GB1 and Tf lead to the conclusion the *Caldibacillus* genus description should be amended to include anaerobic metabolism as a characteristic possible for members of the genus. With respect to co-culturing with the obligate anaerobe *C. thermocellum*, this ability to grow anaerobically as well as aerobically might be crucial in providing an appropriate environment to permit the growth of *C. thermocellum* under aerobic conditions.

The *C. debilis* GB1 is interesting as a candidate for co-culture with *C. thermocellum* for the purpose of ethanol production as *C. debilis* increases total substrate consumption, total ethanol production, ethanol production efficiency, and lends aerotolerance under required conditions. Facultative anaerobes make good co-cultures for strict anaerobes in CBP as they can counteract the toxic effects of oxygen making lab manipulation easier and increasing the inoculation efficiency, a topic seldom dealt with within the literature. Aerobicity is an interesting parameter to experiment with during CBP, and could be manipulated to push cell regulation or biofuel production in new ways. Zuroff *et al.* (2013) used microaerobic conditions to allow both a clostridium and yeast to grow under microaerobic conditions and produce ethanol. We were able to create conditions analogous to this with *C. thermocellum* and *C. debilis* GB1. While able to achieve aerotolerance in the co-cultures, the only benefits seen were to ethanol production under anaerobic conditions. The ability for *C. thermocellum* to grow, metabolise, and produce ethanol, and hydrogen under aerobic conditions with the help of GB1was definitively demonstrated through our work. However, while oxygen was present, the yields of ethanol during cellulose fermentation were lower when compared to the same co-culture under anaerobic conditions.

The Omics used to characterize and understand *C. debilis* gave general insight into aerobic/anaerobic regulation of *Caldibacillus*, and show how similar it is between Firmicutes versus Proteobacteria; mesophilic versus thermophilic bacteria. Furthermore the Omics information produced can also be used in the future for *in silico* bioprospecting.

In view of our work, *Geobacillus* and related thermophilic bacilli appear to be under exploited as CBP co-culture partners. Our characterisation of *C. debilis* enhances the ability for others to choose ideal co-culture partners from pools of interesting organisms for CBP

6.5. Future Perspectives

In order to make CBP work, we need to study different modes of operation with many different bacteria. A crucial element of this is the use of bioprospecting, with different organisms being tried under different operating modes. In concert with this, it is important to understand the core metabolism and regulation of these organisms in order to exploit them effectively under bioprocessing conditions. With respect to central metabolism, it has been demonstrated that *Caldibacillu*s works and acts similarly to other well studied facultative anaerobes: *E. coli* K-12 and *B. cereus*. Others have demonstrated genetic malleability in *Caldibacillus* related genera (Cripps et al. 2009), and in *Caldibacillus debilis* GB1 as well (Wan *et al.* 2013). The literature shows potential for facultative anaerobes to be obligate fermenters (Day *et al.* 2014) under aerobic conditions through either natural mutations and/or directed genetic modifications. Creation of a facultative anaerobe genetically modified to be an obligate fermenter with high ethanol production would be a highly beneficial co-culture partner for *C. thermocellum.* This could also be applied to other strictly anaerobic cellulolytic candidates for CBP under either anaerobic or oxygen limiting conditions. Indeed there has been some work on this with *G. thermoglucosidasius*

being used to create ethanol at high efficiency (Cripps *et al.* 2009). The approaches of genetic modification and co-culturing should dovetail, in the future there will be more studies on co-cultures where both members have been genetically modified for optimization (Argyros *et al.* 2011). The omics information created to understand organisms in pure culture should also be compared against omics data of co-cultures to further understand organism(s) interactions and how they can synergize.

CBP research may be very far, in terms of biofuel yields, from making the CBP processes work commerically; in many cases yields need to improve by large amounts (Jouzani *et al.* 2015). Incremental improvements of single digit percent would prevent rapid implementation of CBP. To achieve the goal of CBP quickly, we should instead focus on innovations that could cause large changes in production. However, such innovations are not entirely obvious at the present time. Experimenting with different CBP modes and organism combinations, and understanding the organisms involved, might permit further improvements in CBP.

Appendices

Appendix A: Physiological and Genomic Characterization of Fervidobacterium pennivorans strain DYC in Relation to the Type Strain[5]

A.1. Abstract

A strictly anaerobic thermophilic cellobiose degrading consortium from Ngatamariki Hot Spring in New Zealand was enriched. Repeated serial dilution of the enrichment culture led to the isolation of a strain of *Fervidobacterium pennivorans*, designated strain DYC. When fermentation profiles were analyzed, DYC was found to produce chromatographic profiles consistent with acetate, alanine, glutamate, H_2, and CO_2 as major end-products on 2g/l cellobiose in modified 1191 medium. The purified strain was sequenced by PacBio sequencing and assembled using Hierarchical Genome Assembly Process (HGAP) into a single 2.06Mbp circularized chromosome, annotated using genePRIMP, and submitted to Integrated Microbial Genomes Expert Review (IMG-er) platform. Comparison of *F. pennivorans* DYC against the type strain *F. pennivorans* DSM 9078 genome using dot plot revealed that these organisms are highly syntenic, and genome to genome distance calculator

Contributions: [a]First author experimental design, cell growth and end-product analysis; worked in concert with others authors in analysis of genome and proteome [b]proteomic tools and expertise, data analyses, and running samples on MS/MS; [c]Bioinformatic tools and expertise, genome assembly and 1st draft annotation; [d]Lab space, equipment, funding, research guidance.

analysis revealed that these organisms are likely the same species. Upon unique genome overlay using Gview, several large ~50kbp areas were distinct in each organism. The differences observed corresponded to differences noted in general physiology of substrate utilization, and end-product production for both the type strain 9078 and DYC. Of particular interest are differences in the Entner-Doudoroff pathway between the strains resulting in the inability of one strain to utilize gluconate. We produced genomic and proteomic data and interpreted it through the lens of our end-product data in order to understand the pathways likely involved in fermentation of sugar substrates.

A.2. Introduction

Fervidobacterium pennivorans is a strictly anaerobic thermophilic bacteria that falls within the order Thermotogales, and has the distinctive loose outer membrane known as a toga (Friedrich *et al.* 1996). *F. pennivorans* is typically isolated from hot springs and grows at an optimum temperature of ~70ºC (Friedrich *et al.* 1996). *F. pennivorans* strains have a wide substrate usage range allowing them to use many sugar monomers, polysaccharides, and complex protein substrates (Nam *et al.* 2002). There has been limited work on characterizing *Fervidobacterium* physiology. However, its ability to hydrolyze substrates, especially recalcitrant proteins, has been a prominent feature (Friedrich *et al.* 1996, Nam *et al.* 2002). *F. pennivorans* has been shown to produce end-products H_2, CO_2, lactate, acetate, and alanine (Ravot *et al.* 1996). The possibility of H_2 from sugars and recalcitrant protein substrates make *F.*

pennivorans a candidate worthy of characterization from a biofuels perspective. *F. pennivorans* has also been a source of thermostable enzymes such as pullulanases, keratinases (Bertoldo *et al.*1999, Nam *et al.* 2002). While major end-products from glucose fermentation have been described previously, at least in part (Ravot *et al.* 1996, Friedrich *et al.* 1996), there has been no attempt to complete a carbon and redox balance in the species *F. pennivorans. Fervidobacterium* core metabolic pathways has yet to be elucidated making it an interesting organism to characterize from a cell metabolism perspective, especially concerning alanine since alanine, as a major fermentation end-product, has been hypothesized to be a remnant of ancestral metabolism (Ravot *et al.* 1996). Alanine production as fermentation product does not appear to be rare as there are many examples of alanine production thermophiles and hyperthermophiles, which include *C. thermocellum, Pyrococcus furiosus,* and *Thermococcus kodakarensis* (Van Der Veen *et al.* 2013, Kengen *et al.* 1994, Nohara *et al.* 2014). While the production of alanine is well documented in *Thermatogales*, it is unclear whether the pathways used in *F. pennivorans* are similar to other thermophiles. We wished to characterize and compare our organism's fermentation profile and genetic complement to see if it fit conventional pathways of end-product production in hyperthermophiles. There has been limited work on the characterization of *F. pennivorans* as an organism (Ravot *et al.* 1996, Friedrich *et al.* 1996). Comparison of two closely related strains physiology through the lens of a genomic comparison can lead to furthering the understanding of core metabolism, especially if the gene complement between two strains is different concerning core metabolism. The chimeric nature of Thermotogales can lead to extensive differences at the whole

genome level between closely related members (Zhaxybayeva *et al.* 2009). The limited characterizing of metabolism, possibility for industrial usefulness, and chimeric genome properties make a genome and physiological comparison of two closely related strains of *F. pennivorans* interesting.

A.3. Materials and Methods

A.3.1. Isolation of DYC and Cell Culturing

Samples including soil and water collected from Ngatamariki Hot Springs in New Zealand in March, 2012. Samples were collected anaerobically and stored in sealed containers without airspace at 4ºC until inoculation. The base medium produced for all experiments was as previously described (Chapter 2), modified 1191 medium, with a lower concentration of yeast extract (0.76 g/l) and pH adjusted to 7.2. Sugars glucose, cellobiose, gluconate, xylose, and ribose were used as primary carbon and energy source (at 2 g/L) as specified for experiments. Sample liquid, or a slurry created using sample water and soil was inoculated at 10% in M-1191 medium in anaerobic Balch tubes with 2g/l cellobiose at 80ºC. Plating this enrichment did not result in colonies. The Ngatamariki Hot Springs enrichment was serial diluted to extinction 10 times in order to create a pure culture designated DYC.Cultures of *F. pennivorans* DSM 9087 were obtained from the DSM culture collection

A.3.2. Cell Growth and Measurement

Prior to each experiment cells were passaged once under the relevant condition to allow adaption to substrate. All experiments were carried out in triplicate using a 1% inoculum. All cultures were grown at 75ºC. Cultures grown for end-product sampling were grown with sampling points at 80 hours post-inoculation (h pi) in sealed aerobic Balch tubes containing 10 ml of media and 17 ml headspace. Optical density OD_{600} was used to monitor cell growth in liquid media with soluble substrates. Protein concentrations were estimated by Bradford Assay (Bradford 1976), using a NanoDrop 1000 spectrometer.

A.3.3. Sugar and End-Product Analysis

Culture samples (1 ml) were collected after 80 h pi and stored at -20ºC until analysed. Concentrations of cellobiose, glucose, gluconate, lactate, formate, acetate, ethanol, butyrate, and butanol were measured directly by high pressure liquid chromatography (HPLC) using a Dionex ICS 3000 system equipped with a Bio-rad Aminex-87H column, and run at 30ºC, 0.75 ml/min, with 0.02 mM sulfuric acid. A Shodex 101 Refractive Index Detector was used on all compounds being analysed. Several amino acids could be quantified indirectly on the same system by their conversion via the van Slyke reaction (Pleissner *et al.* 2010) to compounds that could be eluted, detected, and quantified with our system including: glycine, alanine, valine, leucine, isoleucine, methionine, serine, threonine, asparagine, glutamine, aspartic

acid, glutamic acid, and proline. Using this method, only peaks associated with glutamate and alanine were detected.

Measurements of CO_2, H_2, and O_2 concentrations were determined using a Multiple Gas Analyzer #1 Gas Chromatograph (GC) System Model 8610-0070 (SRI Instruments, Torrance, CA), equipped with a Thermal Conductivity Detector (TCD), and using argon as the carrier gas. Columns and methods were used as previously described by Wushke *et al*. (Chapter 3).

Carbon balance was estimated from end-products produced using the formula: glucose equivalents consumed = $(C_1/6) + (C_2/3) + (C_3/2) + (C_5*(5/6))$. C_1= CO_2, C_2= acetate, and C_3= alanine C_5=Glutamate (Wushke *et al.* 2015). This was then divided by the glucose equivalents consumed as measured by HPLC to give us a percent of carbon converted to end-products.

O/R index was calculated by dividing the oxidized major end products by the reduced products modulated by their oxidation numbers to give redox balance= $(2*CO_2)/H_2$ (Chapter 3)

A.3.4. Genome Sequencing

Cells were grown aerobically on M-1191 medium and cell pellets harvested during mid-exponential phase extraction of DNA. For genomic DNA a Promega wizard genomic extraction kit (Promega) was used and protocol followed as described by the manufacture. DNA was sequenced at Genome Quebec Innovation Centre by PacBio sequencing and assembled using Hierarchical Genome Assembly Process

(HGAP) into a single 2.1Mbp circularized chromosome, annotated using genePRIMP, then submitted NCBI under the accession # CP011393 and to Integrated Microbial Genomes Expert Review (IMG-er) platform.

A.3.5. Comparative Genomics

Comparative genomics were done using IMG (Markowitz *et al*. 2008), Gview (Petkau *et al.* 2010), Genome to Genome Distance Calculator (GGDC) (Meier-Kolthoff *et al.* 2013) using similar methods to those described previously by Wushke *et al.* (Chapter 5). We used MEGA4 for building our 16s rRNA gene tree (Tamura *et al.* 2011) using the neighbour joining method. Metacyc was used for pathway building of the publically available 9078 genome (Caspi *et al.* 2008).

A.3.6. Proteomics

Protein extraction, proteomic analysis, mass spectrometry, and data analysis using UNITY was done on *F. pennivorans* DSM 9078 during mid exponential using methods identical to those described by Wushke *et al*. (Chapter 5).

A.4. Results

A.4.1. Isolation and Initial Growth Characteristics

An enrichment was created using a 10% inoculum of Ngatamariki Hot Springs water in 1191 media with 2g/l cellobiose at 80ºC. This enrichment was serial diluted to extinction 10 times in order to create a pure culture. Both strains 9078 and DYC were pleomorphic and consistent with the literature (Friedrich *et al.* 1996) showing L-shaped rod pairs, large ~10um spheroid structures produced by swelling of the OM, and spheroid structures with elongated cells wrapped around in a yarn-like structure. Growth rate was not statistically different as measured by total protein, results not shown. *F. pennivorans DSM* 9078 and DYC grew well on cellobiose, glucose, and xylose, shown in Figure A.1 but did not grow on ribose under our conditions, data not shown. Addition of thiosulfate as a potential electron acceptor did not appear to stimulate growth to a statistically significant degree in either strain when added as an electron acceptor at 2mM along with glucose. Only 9078 appeared to grow on gluconate, although poorly, as seen in Figure A.1. Growth of 9078 on xylose was primarily homoacetogenic, growth of DYC on xylose was primarily homoalanineogenic.

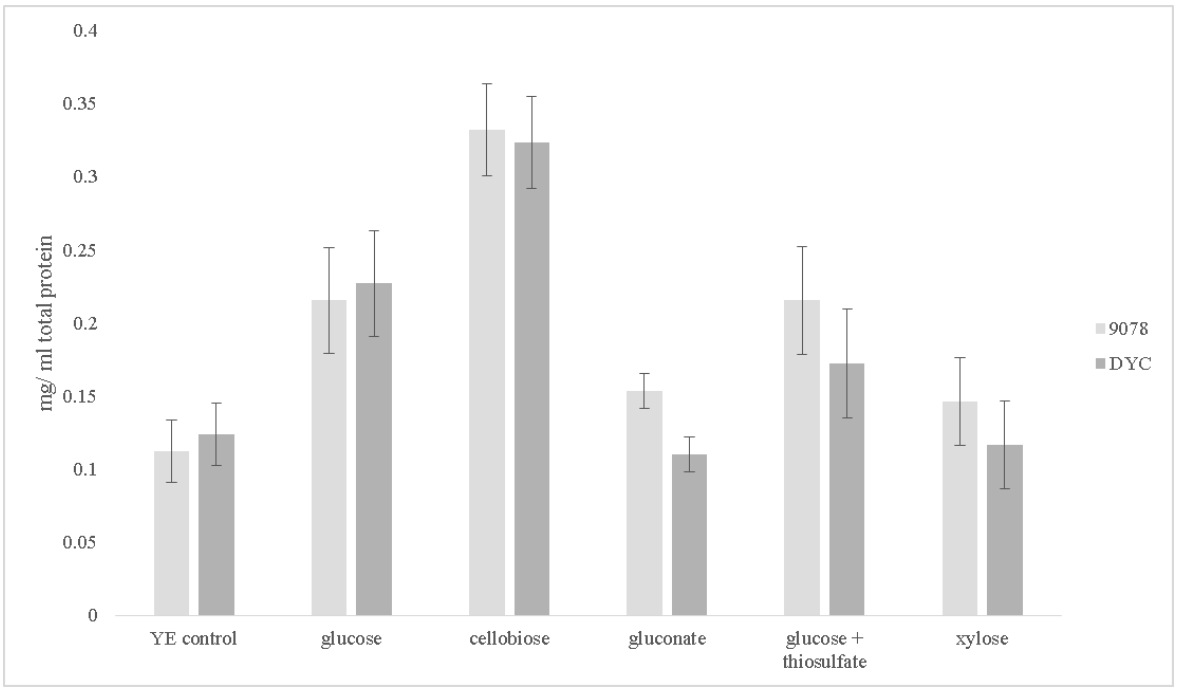

Figure A.1. 9078 and DYC max total protein at 24H pi

A.4.2. *F. pennivorans* DSM 9078 and DYC Relatedness

In order to determine the relatedness of strain DYC to other organisms, we employed four methods: i) compared the two copies of 16s rRNA in each organism and found a sequence similarity of 99% to the type strain of *Fervidobacterium pennivorans,* ii) used MEGA 4 to create a phylogenetic tree of related *Fervidobacterium* 16s rRNA species shown in Figure A.2, iii) used Dot plot with 9078 and *F. nosodum,* whose genome is also complete, to get an idea of synteny and relatedness which showed a much higher degree of synteny with 9078 then with *F. nosodum* at the whole genome level, results are shown in Figure A.3, iv) used GGDC analysis to determine that 9078 and DYC should indeed be considered the same species when considering the entirety of their genomes, results shown in Table A.1. The low formula 2 score (DDH >70%), in Table A.1, indicates that gene sequences have diverged and would not be considered the same species based on formula 2. This would be consistent with the isolation of these two strains from hot springs at distant geographic locations: the Azore Islands, Portugal for the type strain and New Zealand for strain DYC.

A.4.3. *F. pennivorans* DSM 9078 and DYC Genome Comparison

Table A.2 gives general statistics on 9078 and DYC including genome size, number of coding genes, and GC content. Strain 9078 and DYC were both assembled into one single circular chromosome and have a genome size of 2.16 and 2.06 Mbp respectively. Strain 9078 has 281 unique genes coding genes at a ≤60% sequence similarity with DYC, DYC has 123 unique genes at a ≤60% sequence similarity with 9078. The amount of unique genes increases significantly at a ≤90% sequence cut off to 595 and 398 for 9078 and DYC respectively. Figure A.4 is a Venn diagram of the shared and unique genes in DYC and 9078. Tables A.3 and A.4 list the genes unique to 9078 and DYC at a ≤60% sequence similarity cut off. Figure A.5 is a graphical representation of the unique genome of 9078 and DYC at ≤90% amino acid (AA) sequence similarity. Figure A.5 shows there are several large contiguous regions consistent with lateral or horizontal gene transfer as observed in other Thermotogales (Zhaxybayeva *et al.* 2009). A list of 9078 and the corresponding locus tags in DYC can be found in Table A.5. Pathways (Figures A.6, A.9, A.10, A.11, A.12) are based on the 9078 locus tags as it appeared to better fill out the pathways our study was interested in and bring attention to features in DYC that do not match.

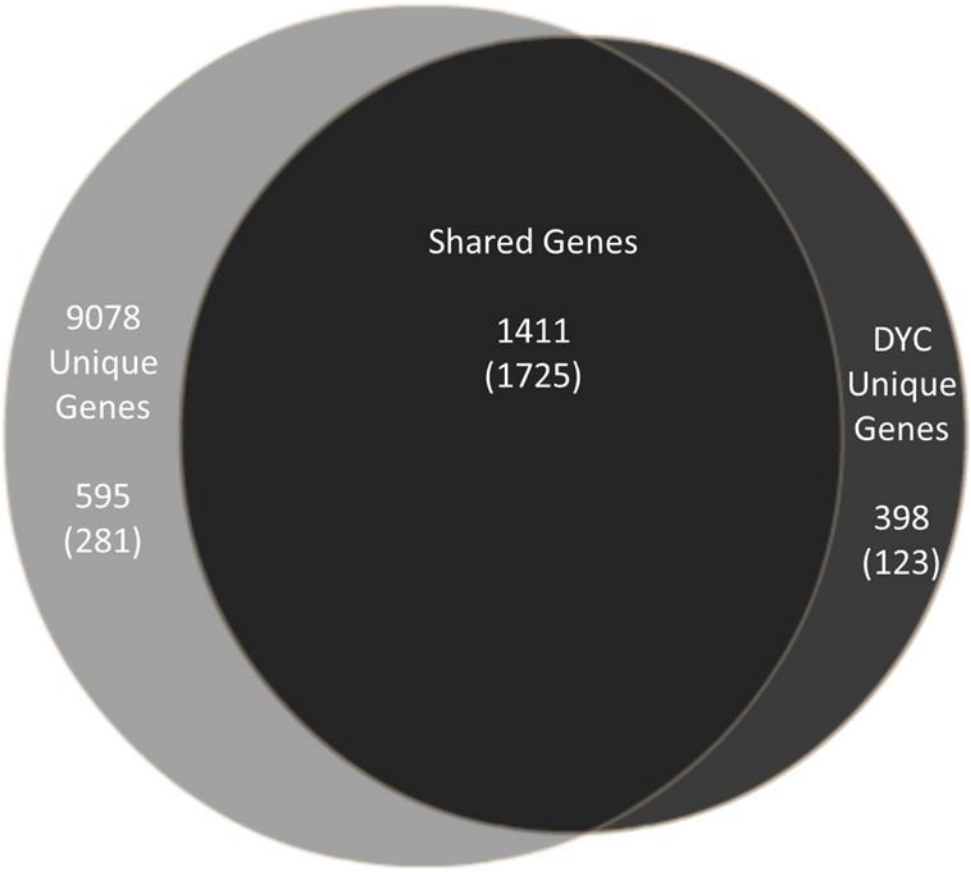

Figure A.4. Unique genes for 9078 and DYC at the ≤90% (≤60%) sequence similarity level

Locus Tag	Gene description
Ferpe_0018	PAS domain S-box-containing protein
Ferpe_0020	Transposase InsO and inactivated derivatives
Ferpe_0081	two-component system, OmpR family, phosphate regulon sensor histidine kinase PhoR
Ferpe_0084	ribonuclease HI
Ferpe_0103	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_0107	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_0108	oligosaccharide repeat unit polymerase
Ferpe_0109	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_0111	hypothetical protein
Ferpe_0112	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_0113	hypothetical protein
Ferpe_0114	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_0115	glucose-1-phosphate thymidylyltransferase
Ferpe_0116	dTDP-4-amino-4,6-dideoxygalactose transaminase
Ferpe_0117	galactoside O-acetyltransferase
Ferpe_0118	dTDP-glucose 4,6-dehydratase
Ferpe_0120	hypothetical protein
Ferpe_0124	Transposase and inactivated derivatives
Ferpe_0128	hypothetical protein
Ferpe_0133	Lactate dehydrogenase
Ferpe_0134	gluconokinase
Ferpe_0135	GntR family transcriptional regulator, transcriptional repressor for pyruvate dehydrogenase complex
Ferpe_0136	2-dehydro-3-deoxyphosphogluconate aldolase / (4S)-4-hydroxy-2-oxoglutarate aldolase
Ferpe_0137	gluconokinase
Ferpe_0138	putative tricarboxylic transport membrane protein
Ferpe_0139	Tripartite-type tricarboxylate transporter, receptor component TctC

Ferpe_0140	Tripartite tricarboxylate transporter TctB family protein
Ferpe_0141	6-phosphogluconate dehydrogenase
Ferpe_0144	transcriptional attenuator, LytR family
Ferpe_0146	hypothetical protein
Ferpe_0149	mannose-1-phosphate guanylyltransferase
Ferpe_0152	ribokinase
Ferpe_0153	transcriptional regulator, LacI family
Ferpe_0154	monosaccharide ABC transporter substrate-binding protein, CUT2 family
Ferpe_0155	ribose transport system permease protein
Ferpe_0156	monosaccharide ABC transporter ATP-binding protein, CUT2 family
Ferpe_0157	D-ribose pyranase
Ferpe_0158	putative pyruvate formate lyase activating enzyme
Ferpe_0159	hypothetical protein
Ferpe_0161	hypothetical protein
Ferpe_0194	carbohydrate ABC transporter membrane protein 1, CUT1 family
Ferpe_0252	N-acetylglucosaminyl deacetylase, LmbE family
Ferpe_0254	hypothetical protein
Ferpe_0308	hypothetical protein
Ferpe_0356	hypothetical protein
Ferpe_0366	Transposase InsO and inactivated derivatives
Ferpe_0391	DNA-binding transcriptional regulator, MarR family
Ferpe_0403	Transposase
Ferpe_0410	Sugar kinase of the NBD/HSP70 family, may contain an N-terminal HTH domain
Ferpe_0451	hypothetical protein
Ferpe_0458	hypothetical protein
Ferpe_0480	flagellar protein FliO/FliZ
Ferpe_0512	UDP-GlcNAc:undecaprenyl-phosphate GlcNAc-1-phosphate transferase
Ferpe_0548	hypothetical protein
Ferpe_0549	hypothetical protein

Ferpe_0550	Protein of unknown function (DUF3298)
Ferpe_0554	type I restriction enzyme, S subunit
Ferpe_0555	type I restriction enzyme, R subunit
Ferpe_0556	hypothetical protein
Ferpe_0557	hypothetical protein
Ferpe_0560	hypothetical protein
Ferpe_0563	hypothetical protein
Ferpe_0564	DNA phosphorothioation system restriction enzyme
Ferpe_0565	hypothetical protein
Ferpe_0566	DNA sulfur modification protein DndD
Ferpe_0567	hypothetical protein
Ferpe_0568	Adenine specific DNA methylase Mod
Ferpe_0569	Type I site-specific restriction-modification system, R (restriction) subunit and related helicases
Ferpe_0572	hypothetical protein
Ferpe_0574	Outer membrane protein assembly factor BamB, contains PQQ-like beta-propeller repeat
Ferpe_0575	PAS domain S-box-containing protein
Ferpe_0578	Alpha/beta hydrolase family protein
Ferpe_0579	hypothetical protein
Ferpe_0581	glutamine amidotransferase
Ferpe_0584	CAAX protease self-immunity
Ferpe_0585	hypothetical protein
Ferpe_0586	hypothetical protein
Ferpe_0587	hypothetical protein
Ferpe_0588	putative transposase
Ferpe_0589	CAAX protease self-immunity
Ferpe_0590	hypothetical protein
Ferpe_0591	hypothetical protein
Ferpe_0592	CAAX protease self-immunity
Ferpe_0593	hypothetical protein
Ferpe_0619	prepilin-type N-terminal cleavage/methylation domain-containing protein

Ferpe_0657	Putative F0F1-ATPase subunit Ca2+/Mg2+ transporter
Ferpe_0665	Diguanylate cyclase, GGDEF domain
Ferpe_0667	signal peptidase II
Ferpe_0668	Cd2+/Zn2+-exporting ATPase
Ferpe_0669	transcriptional regulator, ArsR family
Ferpe_0670	Site-specific DNA recombinase
Ferpe_0671	hypothetical protein
Ferpe_0672	Recombinase zinc beta ribbon domain-containing protein
Ferpe_0677	hypothetical protein
Ferpe_0685	Transposase
Ferpe_0686	DNA replication protein DnaC
Ferpe_0689	Acetyltransferases, including N-acetylases of ribosomal proteins
Ferpe_0691	NAD+ synthase (glutamine-hydrolysing)
Ferpe_0695	thiamine diphosphokinase
Ferpe_0697	regulator of sigma E protease
Ferpe_0701	large conductance mechanosensitive channel
Ferpe_0702	Beta-propeller repeat-containing protein
Ferpe_0705	anaerobic ribonucleoside-triphosphate reductase activating protein
Ferpe_0706	serine O-acetyltransferase
Ferpe_0707	cysteine synthase A
Ferpe_0708	butyryl-CoA dehydrogenase
Ferpe_0709	electron transfer flavoprotein beta subunit
Ferpe_0710	electron transfer flavoprotein alpha subunit apoprotein
Ferpe_0712	Outer membrane protein assembly factor BamB, contains PQQ-like beta-propeller repeat
Ferpe_0713	hypothetical protein
Ferpe_0714	Outer membrane protein assembly factor BamB, contains PQQ-like beta-propeller repeat
Ferpe_0715	VanZ like family protein
Ferpe_0716	hypothetical protein
Ferpe_0717	Uncharacterized conserved protein, DUF58 family, contains vWF domain
Ferpe_0721	hypothetical protein

Ferpe_0729	Transposase
Ferpe_0730	DNA replication protein DnaC
Ferpe_0731	protein of unknown function
Ferpe_0732	hypothetical protein
Ferpe_0736	transcriptional attenuator, LytR family
Ferpe_0738	Predicted ATPase, AAA+ ATPase superfamily
Ferpe_0740	opine dehydrogenase
Ferpe_0741	Predicted cobalamin binding protein
Ferpe_0742	D-alanine-D-alanine ligase
Ferpe_0744	hypothetical protein
Ferpe_0745	hypothetical protein
Ferpe_0746	hypothetical protein
Ferpe_0747	Uncharacterized protein YydD, contains DUF2326 domain
Ferpe_0748	adenine-specific DNA-methyltransferase
Ferpe_0749	type III restriction enzyme
Ferpe_0785	diguanylate cyclase (GGDEF) domain-containing protein
Ferpe_0807	hypothetical protein
Ferpe_0808	multiple sugar transport system permease protein
Ferpe_0809	ABC-type sugar transport system, permease component
Ferpe_0810	hypothetical protein
Ferpe_0811	Gluconolactonase
Ferpe_0814	ABC-type glycerol-3-phosphate transport system, substrate-binding protein
Ferpe_0815	multiple sugar transport system substrate-binding protein
Ferpe_0816	Cellobiose phosphorylase
Ferpe_0817	beta-galactosidase
Ferpe_0818	transcriptional regulator, LacI family
Ferpe_0826	TusA-related sulfurtransferase
Ferpe_0827	tRNA 2-thiouridine synthesizing protein B
Ferpe_0828	tRNA 2-thiouridine synthesizing protein C
Ferpe_0829	tRNA 2-thiouridine synthesizing protein D
Ferpe_0830	hypothetical protein

Ferpe_0831	TusA-related sulfurtransferase
Ferpe_0847	transcriptional regulator, LacI family
Ferpe_0848	beta-galactosidase
Ferpe_0896	HDIG domain-containing protein
Ferpe_0905	hypothetical protein
Ferpe_0906	Predicted heme/steroid binding protein
Ferpe_1019	Uncharacterized lipoprotein YddW, UPF0748 family
Ferpe_1028	hypothetical protein
Ferpe_1056	Rod binding protein
Ferpe_1061	acyl-phosphate glycerol 3-phosphate acyltransferase
Ferpe_1062	hypothetical protein
Ferpe_1067	Predicted oxidoreductases of the aldo/keto reductase family
Ferpe_1068	hypothetical protein
Ferpe_1069	Transposase
Ferpe_1070	DNA replication protein DnaC
Ferpe_1071	hypothetical protein
Ferpe_1072	ATP-binding cassette, subfamily C
Ferpe_1073	ABC transporter transmembrane region
Ferpe_1074	ATP-binding cassette, subfamily C
Ferpe_1082	hypothetical protein
Ferpe_1101	hypothetical protein
Ferpe_1102	4-alpha-L-fucosyltransferase glycosyl transferase group 56
Ferpe_1103	Glucose-1-phosphate thymidylyltransferase
Ferpe_1104	dTDP-4-amino-4,6-dideoxygalactose transaminase
Ferpe_1105	galactoside O-acetyltransferase
Ferpe_1106	dTDP-glucose 4,6-dehydratase
Ferpe_1107	hypothetical protein
Ferpe_1109	Membrane protein involved in the export of O-antigen and teichoic acid
Ferpe_1110	Glycosyl transferases group 1
Ferpe_1111	Glycosyltransferases, probably involved in cell wall biogenesis
Ferpe_1112	osmoprotectant transport system substrate-binding protein

Ferpe_1113	osmoprotectant transport system permease protein
Ferpe_1114	osmoprotectant transport system ATP-binding protein
Ferpe_1115	osmoprotectant transport system permease protein
Ferpe_1127	Transposase
Ferpe_1133	S-layer homology domain-containing protein
Ferpe_1145	poly-gamma-glutamate synthesis protein (capsule biosynthesis protein)
Ferpe_1160	butyryl-CoA dehydrogenase
Ferpe_1161	electron transfer flavoprotein beta subunit
Ferpe_1162	electron transfer flavoprotein alpha subunit apoprotein
Ferpe_1163	Major Facilitator Superfamily protein
Ferpe_1170	Uncharacterized protein YvpB
Ferpe_1180	PQQ-like domain-containing protein
Ferpe_1199	H+/Cl- antiporter ClcA
Ferpe_1219	hypothetical protein
Ferpe_1223	hypothetical protein
Ferpe_1224	prepilin-type N-terminal cleavage/methylation domain-containing protein
Ferpe_1225	hypothetical protein
Ferpe_1226	Repeat domain-containing protein
Ferpe_1228	transcriptional regulator, LacI family
Ferpe_1229	ribose 5-phosphate isomerase B
Ferpe_1230	hypothetical protein
Ferpe_1231	alpha-glucosidase
Ferpe_1232	transketolase
Ferpe_1233	transketolase
Ferpe_1234	alcohol dehydrogenase
Ferpe_1235	EamA-like transporter family protein
Ferpe_1236	oligogalacturonide transporter
Ferpe_1237	multiple sugar transport system permease protein
Ferpe_1238	carbohydrate ABC transporter membrane protein 1, CUT1 family
Ferpe_1239	multiple sugar transport system substrate-binding protein
Ferpe_1342	Serine protease, subtilisin family

Ferpe_1343	Carboxypeptidase regulatory-like domain-containing protein
Ferpe_1360	RNAse III
Ferpe_1456	hypothetical protein
Ferpe_1461	peptide/nickel transport system permease protein
Ferpe_1476	hypothetical protein
Ferpe_1481	hypothetical protein
Ferpe_1483	AAA domain-containing protein
Ferpe_1488	predicted D-glycerate permease
Ferpe_1503	segregation and condensation protein B
Ferpe_1524	peptidoglycan L-alanyl-D-glutamate endopeptidase CwlK
Ferpe_1525	hypothetical protein
Ferpe_1526	Helix-turn-helix
Ferpe_1527	Dipeptidyl aminopeptidase/acylaminoacyl peptidase
Ferpe_1528	peptidoglycan L-alanyl-D-glutamate endopeptidase CwlK
Ferpe_1536	CRISPR-associated protein, Cmr2 family
Ferpe_1537	CRISPR-associated protein, Cmr1 family
Ferpe_1540	CRISPR-associated endoribonuclease Cas6
Ferpe_1568	hypothetical protein
Ferpe_1569	hypothetical protein
Ferpe_1570	hypothetical protein
Ferpe_1573	hypothetical protein
Ferpe_1575	hypothetical protein
Ferpe_1576	hypothetical protein
Ferpe_1577	hypothetical protein
Ferpe_1578	deoxyribodipyrimidine photo-lyase
Ferpe_1579	hypothetical protein
Ferpe_1580	AAA-like domain-containing protein
Ferpe_1585	hypothetical protein
Ferpe_1614	LAO/AO transport system kinase
Ferpe_1658	hypothetical protein
Ferpe_1666	hypothetical protein
Ferpe_1676	Type II secretory pathway, component PulD

Ferpe_1681	Iron-regulated ABC transporter permease protein SufD
Ferpe_1684	energy-coupling factor transport system substrate-specific component
Ferpe_1685	energy-coupling factor transport system permease protein
Ferpe_1686	energy-coupling factor transport system ATP-binding protein
Ferpe_1687	energy-coupling factor transport system ATP-binding protein
Ferpe_1708	energy-coupling factor transport system permease protein
Ferpe_1711	DNA methylase
Ferpe_1713	Transposase
Ferpe_1721	hypothetical protein
Ferpe_1727	phosphoribosyl-ATP pyrophosphatase
Ferpe_1730	regulatory protein, Fis family
Ferpe_1733	ATP-dependent exoDNAse (exonuclease V) beta subunit (contains helicase and exonuclease domains)
Ferpe_1745	hypothetical protein
Ferpe_1768	hypothetical protein
Ferpe_1803	transcriptional regulator, MarR family
Ferpe_1820	Na+-dependent transporter, SNF family
Ferpe_1821	hypothetical protein
Ferpe_1822	hypothetical protein
Ferpe_1850	Transposase
Ferpe_1859	Glycosyltransferase involved in cell wall bisynthesis
Ferpe_1860	hypothetical protein
Ferpe_1861	ADP-heptose:LPS heptosyltransferase
Ferpe_1862	hypothetical protein
Ferpe_1863	arabinose-5-phosphate isomerase
Ferpe_1864	Nucleoside-diphosphate-sugar pyrophosphorylase involved in lipopolysaccharide biosynthesis/translation initiation factor 2B, gamma/epsilon subunits (eIF-2Bgamma/eIF-2Bepsilon)
Ferpe_1895	cell division protein FtsW
Ferpe_1923	S-layer homology domain-containing protein
Ferpe_1929	Glyoxylase, beta-lactamase superfamily II
Ferpe_1932	Signal transduction histidine kinase

Ferpe_1937	putative pyruvate formate lyase activating enzyme
Ferpe_1951	protein of unknown function (DUF4897)
Ferpe_1957	PhoPQ-activated pathogenicity-related protein
Ferpe_1958	Cache 3/Cache 2 fusion domain-containing protein
Ferpe_1996	hypothetical protein
Ferpe_1997	Micrococcal nuclease (thermonuclease) homologs
Ferpe_1998	The GLUG motif-containing protein
Ferpe_2001	micrococcal nuclease
Ferpe_2021	multicomponent Na+:H+ antiporter subunit F
Ferpe_2039	hypothetical protein
Ferpe_2059	cell division protein FtsI (penicillin-binding protein 3)
Ferpe_2064	D-amino peptidase

Table A.4. Genes Unique to DYC when Compared to 9078 at a ≤60% Sequence Similarity cut Off

Locus Tag	Gene description
JM64_00410	hypothetical protein
JM64_00535	hypothetical protein
JM64_00540	hypothetical protein
JM64_00545	Cupin domain-containing protein
JM64_00785	CRISPR-associated protein, Cmr1 family
JM64_00905	hypothetical protein
JM64_01180	Polysaccharide deacetylase
JM64_01335	hypothetical protein
JM64_01585	hypothetical protein
JM64_01610	hypothetical protein
JM64_01615	Membrane protein involved in the export of O-antigen and teichoic acid
JM64_01620	Glycosyltransferase involved in cell wall bisynthesis
JM64_01625	Glycosyltransferase involved in cell wall bisynthesis
JM64_01635	hypothetical protein
JM64_01645	hypothetical protein
JM64_01650	hypothetical protein
JM64_01665	Fic/DOC family protein
JM64_01670	hypothetical protein
JM64_01680	hypothetical protein
JM64_01690	hypothetical protein
JM64_01695	Coenzyme F420 hydrogenase/dehydrogenase, beta subunit C terminus
JM64_01700	Polysaccharide pyruvyl transferase
JM64_01705	hypothetical protein
JM64_01720	hypothetical protein
JM64_01730	hypothetical protein
JM64_01735	Glycosyltransferase involved in cell wall bisynthesis
JM64_01740	hypothetical protein
JM64_01745	O-antigen ligase like membrane protein

JM64_01750	Glycosyltransferase involved in cell wall bisynthesis
JM64_01760	hypothetical protein
JM64_01780	Glycosyltransferase involved in cell wall bisynthesis
JM64_02145	LVIVD repeat-containing protein
JM64_02485	hypothetical protein
JM64_02490	Na+-transporting NADH:ubiquinone oxidoreductase subunit F
JM64_02495	Na+-transporting NADH:ubiquinone oxidoreductase subunit E
JM64_02750	Acyl-coenzyme A:6-aminopenicillanic acid acyl-transferase
JM64_02755	two component transcriptional regulator, LytTR family
JM64_02760	Histidine kinase
JM64_02765	hypothetical protein
JM64_02775	hypothetical protein
JM64_02825	hypothetical protein
JM64_02940	beta-galactosidase
JM64_03215	hypothetical protein
JM64_03220	Transposase and inactivated derivatives
JM64_03225	hypothetical protein
JM64_03280	hypothetical protein
JM64_03335	hypothetical protein
JM64_03375	transposase, IS4 family
JM64_03630	prepilin-type N-terminal cleavage/methylation domain-containing protein
JM64_03680	peptide/nickel transport system ATP-binding protein
JM64_03685	ABC-2 type transport system permease protein
JM64_03690	ABC-2 type transport system ATP-binding protein
JM64_03695	carbohydrate ABC transporter substrate-binding protein, CUT1 family
JM64_03825	hypothetical protein
JM64_03840	Mrr N-terminal domain-containing protein
JM64_03845	Mrr N-terminal domain-containing protein
JM64_03850	TaqI-like C-terminal specificity domain-containing protein
JM64_03855	SNF2 family N-terminal domain-containing protein
JM64_03860	UvrD-like helicase C-terminal domain-containing protein
JM64_03865	UvrD/REP helicase N-terminal domain-containing protein

JM64_03880	ATP-dependent DNA helicase RecG
JM64_03900	alkylhydroperoxidase AhpD family core domain-containing protein
JM64_03925	ATP-dependent DNA helicase RecG
JM64_03935	hypothetical protein
JM64_04055	anti-anti-sigma factor
JM64_04260	hypothetical protein
JM64_04425	carbohydrate ABC transporter substrate-binding protein, CUT1 family
JM64_04430	carbohydrate ABC transporter membrane protein 1, CUT1 family
JM64_04450	hypothetical protein
JM64_04720	hypothetical protein
JM64_05330	hypothetical protein
JM64_05340	Protein of unknown function (DUF4230)
JM64_05345	Protein of unknown function (DUF4230)
JM64_05975	Tocopherol cyclase
JM64_06240	hypothetical protein
JM64_06425	hypothetical protein
JM64_06635	peptide/nickel transport system ATP-binding protein
JM64_06640	peptide/nickel transport system ATP-binding protein
JM64_06645	peptide/nickel transport system permease protein
JM64_06650	peptide/nickel transport system permease protein
JM64_06655	peptide/nickel transport system substrate-binding protein
JM64_06725	hypothetical protein
JM64_06735	hypothetical protein
JM64_06740	UDP-galactopyranose mutase
JM64_07095	hypothetical protein
JM64_07290	Sugar kinase of the NBD/HSP70 family, may contain an N-terminal HTH domain
JM64_07295	putative multiple sugar transport system permease protein
JM64_07300	putative multiple sugar transport system ATP-binding protein
JM64_07305	monosaccharide ABC transporter substrate-binding protein, CUT2 family
JM64_07520	branched-chain amino acid transport system ATP-binding protein
JM64_07525	branched-chain amino acid transport system permease protein

JM64_07530	branched-chain amino acid transport system permease protein
JM64_07535	branched-chain amino acid transport system substrate-binding protein
JM64_07540	branched-chain amino acid transport system substrate-binding protein
JM64_07825	D-amino peptidase
JM64_08210	hypothetical protein
JM64_08235	peptide/nickel transport system substrate-binding protein
JM64_08240	peptide/nickel transport system permease protein
JM64_08245	peptide/nickel transport system permease protein
JM64_08250	peptide/nickel transport system ATP-binding protein
JM64_08255	peptide/nickel transport system ATP-binding protein
JM64_08260	BadF-type ATPase
JM64_08265	GntR family transcriptional regulator
JM64_08275	beta-N-acetylhexosaminidase
JM64_08280	Uncharacterized conserved protein YbbC, DUF1343 family
JM64_08285	peptide/nickel transport system substrate-binding protein
JM64_08290	peptide/nickel transport system permease protein
JM64_08300	peptide/nickel transport system permease protein
JM64_08305	oligopeptide transport system ATP-binding protein
JM64_08310	peptide/nickel transport system ATP-binding protein
JM64_08315	CubicO group peptidase, beta-lactamase class C family
JM64_08345	hypothetical protein
JM64_08865	2',3'-cyclic-nucleotide 2'-phosphodiesterase / 3'-nucleotidase
JM64_08880	hypothetical protein
JM64_08910	hypothetical protein
JM64_09725	Serine protease, subtilisin family
JM64_09730	hypothetical protein
JM64_09910	HD domain-containing protein
JM64_09915	hypothetical protein
JM64_09945	hypothetical protein
JM64_09950	hypothetical protein
JM64_09955	hypothetical protein
JM64_09960	hypothetical protein

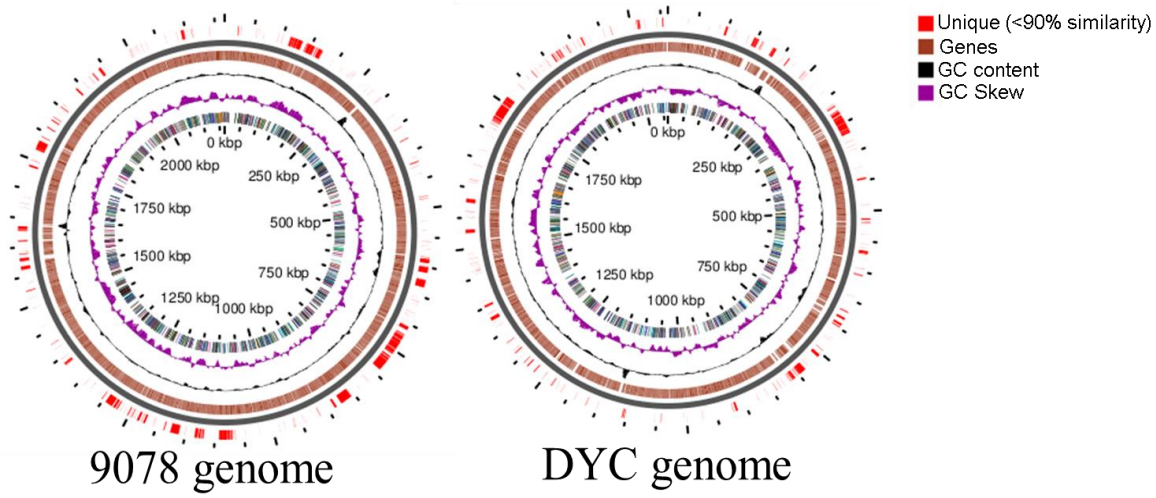

Figure A.5. 9078 and DYC unique genome analysis Areas in red are regions that do not match the corresponding strain at a ≤90% sequence similarity cut off

Table A.5. 9078 and DYC corresponding locus tags at a ≥60% sequence similarity

9078 Locus Tag	DYC Locus Tag	Gene description
Ferpe_0001	JM64_07830	chromosomal replication initiator protein DnaA
Ferpe_0002	JM64_07835	ferredoxin
Ferpe_0003	JM64_07840	hypothetical protein
Ferpe_0004	JM64_07845	nucleoside-binding protein
Ferpe_0005	JM64_07850	nucleoside ABC transporter ATP-binding protein
Ferpe_0006	JM64_07855	nucleoside ABC transporter membrane protein
Ferpe_0007	JM64_07860	nucleoside ABC transporter membrane protein
Ferpe_0008	JM64_07865	secondary thiamine-phosphate synthase enzyme
Ferpe_0009	JM64_07870	DNA-binding protein HU-beta
Ferpe_0010	JM64_07875	HDIG domain-containing protein
Ferpe_0011	JM64_07880	FecR family protein
Ferpe_0012	JM64_07885	Protein of unknown function (DUF3307)
Ferpe_0013	JM64_07890	HD domain-containing protein
Ferpe_0014	JM64_07020	Transposase (or an inactivated derivative)
Ferpe_0015	JM64_07895	adenylate cyclase
Ferpe_0016	JM64_07020	Transposase (or an inactivated derivative)
Ferpe_0017	JM64_07905	secondary thiamine-phosphate synthase enzyme
Ferpe_0019	JM64_07915	Fucose permease
Ferpe_0021	JM64_07920	hypothetical protein
Ferpe_0022	JM64_07925	hypothetical protein
Ferpe_0023	JM64_07930	hypothetical protein

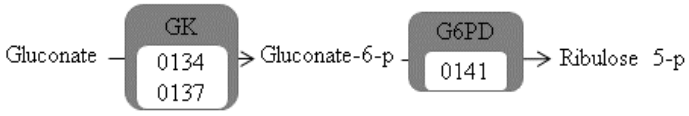
The two strains of Fervidobacterium 9078 and DYC appear to be highly related, yet distinct. In Figure A.5 we noticed 2 large ~50Kbp tracks of DNA unique to each, as well as many small unique tracts of DNA, in some cases a single unique gene being added in an otherwise syntenic area. We assessed whether these unique genes enabled any different functionality from a core metabolism perspective using KEGG pathways overlay available through IMG/er. Several genes in DYC concerning core metabolism appeared to be missing when compared to 9078. Of note, the findings indicated that contained within a large tract of DNA unique to strain 9078 (Ferpe_0103- Ferpe_0194) appeared to have two key enzymes that may allow a full Entner-Doudoroff pathway to function, Gluconate kinase, and Gluconate 6-p dehydrogenase with locus tags Ferpe_0134/0137 and Ferpe_0141 respectively shown in Figure A.6.



GK= gluconate Kinase; G6PD= Gluconate 6-phosphate dehydrogenase

Figure A.6. Entner-Doudoroff pathway present only in 9078

A.4.4. *F. pennivorans* DSM 9078 and DYC End-Product Production

Both 9078 and DYC produce the same major end-product profiles from cellobiose metabolism chromatographically consistent with CO_2, H_2, acetate, alanine, and glutamate production. Major end-products on different substrates are shown in Figure A.7. Both alanine and glutamate were measured indirectly, via van Slyke reaction (Pleissner *et al.* 2010).There were many minor end-product peaks that were below quantification limits, some of them were responsive to the presence of sugar substrate being present such as ethanol, butanol, and butyrate; others were not responsive to sugar substrate being present such as peaks consistent with glycerol (or formate as they co-elute), and many unknown peaks at 10.1, 10.5, 13.1, 14.2, 18.51, 20.03, and 21.49 minutes. The peaks that were not responsive to sugar substrates were assumed to be the result of YE metabolism. Trace butyrate and butanol was observed in growth with 9078 under almost every growth condition when a sugar substrate was present and in DYC under growth on xylose, results shown in Table A.6. Trace ethanol (Table A.7) was produced in DYC under every sugar substrate (with the exception of xylose) and without a sugar substrate. In 9078 trace ethanol was only produced in the presence of cellobiose sugar substrate.

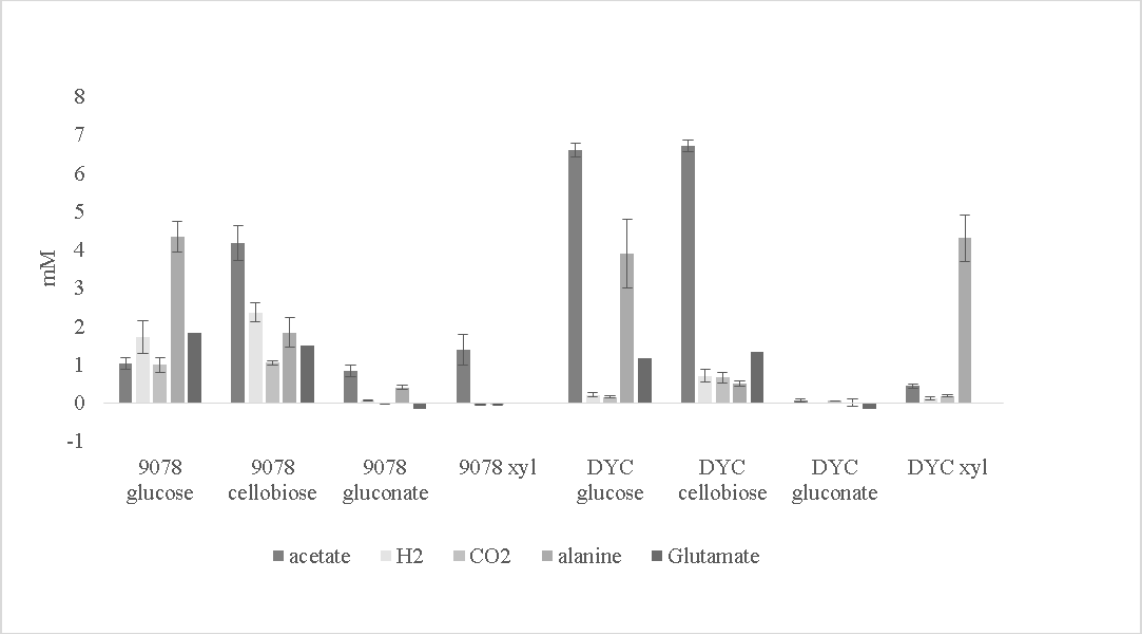


Figure A.7. 9078 vs DYC mM of major end-products yield after 80 hours PI

Table A.6. Presence of trace butyrate/butanol in fermentation profiles using different sugar substrates

Substrate	Trace butyrate	Trace butanol
9078 no sugar substrate	+	+
9078 glucose	+	+
9078 cellobiose	+	-
9078 gluconate	+	+
9078 xylose	+	+
DYC no sugar substrate	-	-
DYC glucose	-	-
DYC cellobiose	-	-
DYC gluconate	-	-
DYC xylose	+	+

Table A.7. Presences of trace ethanol in fermentation profiles using different sugar substrates

Substrate	Trace ethanol
9078 no sugar substrate	-
9078 glucose	-
9078 cellobiose	+
9078 gluconate	-
9078 xylose	-
DYC no sugar substrate	+
DYC glucose	+
DYC cellobiose	+
DYC gluconate	+
DYC xylose	-

A.4.5. Carbon and Redox Balance

Carbon balances, Figure A.8, slightly high and in the ~95-115% range. The only two major end-products which contributed to our redox calculation were CO_2 and H_2 as the other major end-products were redox neutral. O/R balances where an appreciable amount of H_2 and CO_2 were produced (<0.2mM) showed redox balances of 90%+ in all but two case, DYC on cellobiose which had the poorest redox balance of ~50%. As CO_2 and H_2 represented a small amount of total carbon and electrons in many cases the noise to signal ratio was quite high. When considering redox balance the most important observation we made is that the vast majority of end-products produced via sugar fermentation were O/R neutral.

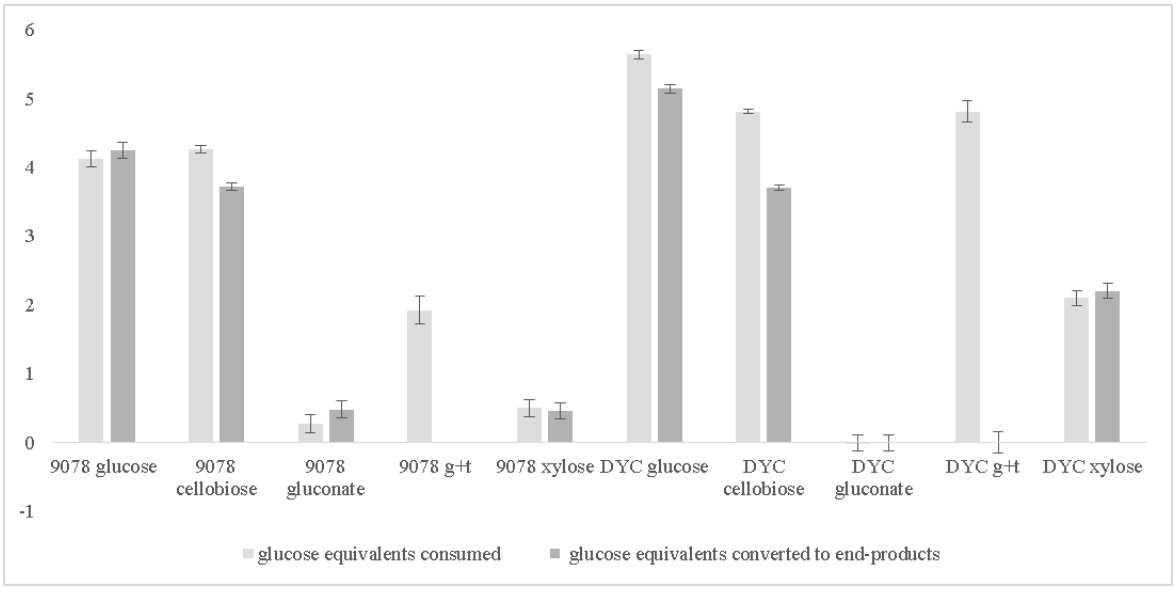

Figure A.8. 9078 vs DYC carbon balances at 80h pi

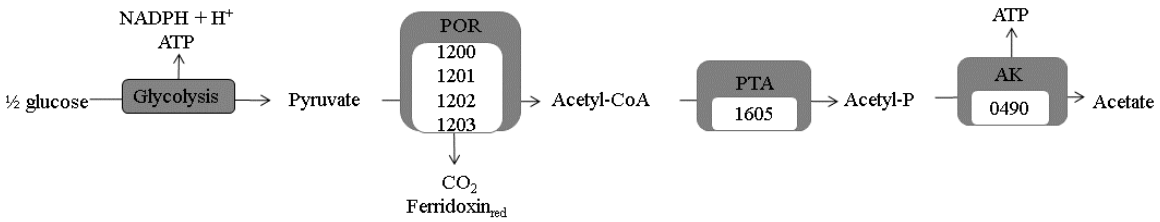
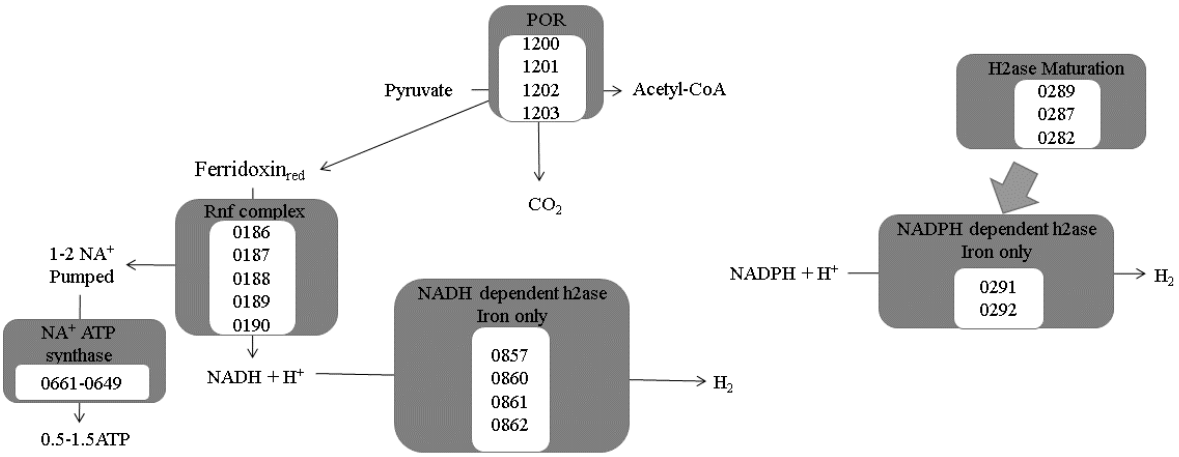
A.4.6. Gene Complement to Produce Major End-products of Interest

F. pennivorans appear to possess the necessary pathways to create the major products acetate, alanine, glutamate, H_2, and CO_2 (Shown in Figures A.9-A.12) and both DYC and 9078 appear to have the same gene complement regarding these products, only the 9078 locus tags are listed but the corresponding locus tag for DYC can be found in Table A.5.



POR= Pyruvate Oxidoreductase; PTA= phosphotransacetylase; AK= Acetate Kinase

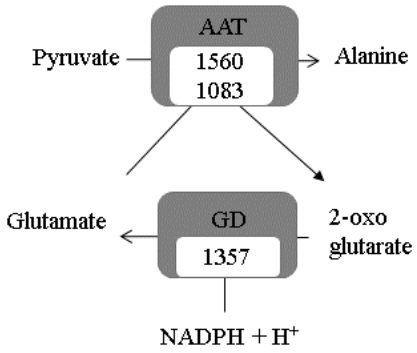
Figure A.9. Proposed pathway of acetate production in 9078 and DYC



POR= Pyruvate Oxidoreductase

Figure A.10. Proposed pathway of RNF and hydrogen production based on gene complement in 9078 and DYC.

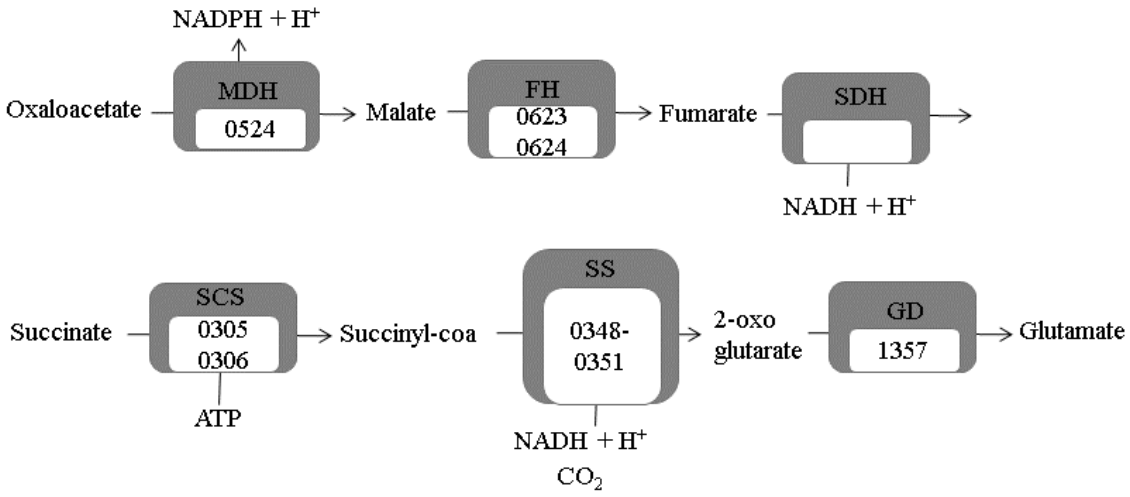
Kengen *et al.* (1994) proposes alanine formation in *Pyrococcus furiosus* via an alanine aminotransferase and glutamate/2 oxo-glutarate cycling via a glutamate reductase shown in Figure A.11. We were able to readily identify a glutamate reductase (Ferpe_1357) but had difficulty identifying an appropriate alanine aminotransferase (AAT). We identified 2 possible genes that could function as AAT and 9078, Ferpe_1560 and Ferpe_1083, which were annotated as aspartate aminotransferases with a 56% AA sequence similarity with *Pyrococcus furiosus's* alanine aminotransferase.



AAT=Alanine Ammonia Transferase; GD= Glutamate dehydrogenase

Figure A.11. Possible mechanism of alanine production in 9078 and DYC based off the mechanism for alanine production in *Pyrococcus furiosus* by Kengen *et al.* (1994)

The pathway used for glutamate production may not be as straight forward as in other organisms. *F. pennivorans* (both DYC and 9078) have an incomplete TCA cycle. *F pennivorans* is missing Citrate synthase, Aconitase, Isocitrate dehydrogenase, and Succinate dehydrogenase. *F. pennivorans* does not appear to produce glutamate via reverse TCA given that it is missing a succinate dehydrogenase gene or fumarate reductase to convert fumarate to succinate (Figure A.12). However Metacyc analysis shows that precursors to glutamate metabolism such as succinyl-CoA can be generated by other mechanisms like methylmalonyl-CoA mutase. *F. pennivorans* does have the genes to convert succinyl-CoA to 2-oxoglutarate and then to glutamate. Regardless of the source of production succinyl-CoA or succinate is necessary for glutamate synthesis, the mechanism for this is unclear.



MDH= Malate dehydrogenase; FH= Fumarate Hydratase; SDH= Succinate dehydrogenase; SCS=Succinate CoA Synthase; SS=Succinate synthase; GD= glutamate dehydrogenase.

Figure A.12. Missing SDH/FR in 9078 and DYC do not allow for synthesis of glutamate through reverse tricarboxylic acid cycle.

A.4.7. Proteomics

We analyzed the proteome of 9078 during exponential phase, Table A.8. We detected and gave TIC scores to 1690/2006 putative proteins giving us 84% proteomic coverage. While most of the highest expressed genes were involved in core metabolism, we were able to pick several highly expressed proteins in the top 20 that were of interest, including: i) ornithine carbamoyltransferase, which is involved in arginine fermentation, ii) serine-pyruvate aminotransferase, which may be involved in alanine production or serine degradation, and iii) a butanol specific alcohol dehydrogenase indicating potential for thermophilic butanol production. We noticed 9078 expressed several sulfide dehydrogenase associated genes amongst the lowest level of detected proteins. Strain 9078 appears to highly express genes needed for both AA fermentation and sugar fermentation. *F. pennivorans* has a small genome and may express a large portion (~ 84% of annotated genes were detected) of it in preparedness for changing conditions; indeed there are other examples of expression stability of thermophilic anaerobes under changing conditions (Verbeke *et al.* 2014).

Table A.8. *F. pennivorans* 9078 log2TIC expression value as measured by proteomics

A.5. Discussion

A.5.1. 9078 and DYC Genome Comparison

The 9078 and DYC genome comparison shows that 9078 and DYC are highly related strains of the same species. They both contain areas that are highly syntenic and regions which are unique, likely due to the chimeric nature of Thermotgales. This allowed for quite different gene complements between the organisms even for genes in core metabolism such as the number of gene copies in the pentose phosphate KEGG map unique to 9078, transketolases (Ferpe_1232, Ferpe_1233), and ribokinase (Ferpe_0152). Difference in pentose phosphate gene numbers could cause the differences we see on end-product production on xylose between the two strains. While lactate production was not observed in our strains under our conditions we also noted that only 9078 appears to have a lactate dehydrogenase (Ferpe_0133); again, this is a gene on a long contiguous region missing from DYC. Overall, 9078 and DYC appear to be quite similar yet distinct strains of the same species.

A.5.2. Gluconate metabolism

Typically gluconate has not been used as a growth substrate in Fervidobacterium, but Entner-Doudoroff activity has been demonstrated in other Thermotogales (Kengen *et al.* 1994, Cappelletti *et al.* 2014). While only 9078 was able to grow on gluconate, its growth was poor relative to its growth on other sugars. This suggests that the Entner-Doudoroff pathway is utilized to only a very limited

degree in 9078 under our conditions. As the end-products of gluconate growth were not more reduced, as would be expected with a more reduced sugar, it is likely that YE metabolism was used to accept the extra electrons from gluconate. This would also explain why 9078 exhibited poor growth as the YE was present in only very small amounts. The ability to grow on gluconate may be a good substrate to compare *Fervidobacterium sp.* on and has not been done previously in the literature.

A.5.3. Major end-products

9078 and DYC appear to have a rather typical mechanism for acetate fermentation, and pathways necessary for hydrogen production. They also may conserve energy through the use of a sodium gradient and the RNF system as many sodium coupled genes were observed in their genomes.

Pyroglutamate production has been reported in other thermophiles such as *C. thermocellum* (Holwerda *et al.* 2014). Glutamate has not been previously described as a major end-product of sugar metabolism in the genus *Fervidobacterium pennivorans*. Typically, glutamate links carbon and nitrogen metabolism in hyperthermophiles (Robb *et al.* 1992). We are unsure about the pathways involved in glutamate production for our strains.

Alanine production is well documented in hyperthermophiles as well as in the present genus (Cappelletti *et al.* 2014). There are very few sequences of confirmed alanine aminotransferases within hyperthermophiles. Given this, it was challenging to make judgement on the quality of the annotation. There are other alanine forming

proteins such as an archaea type serine-pyruvate aminotransferase (SPAT) in both DYC and 9078 that could also be involved in the creation of alanine. Conversely SPAT could be involved in serine fermentation, as a key aspect of this organism's physiology is protein degradation (Friedrich *et al.* 1996).

A.5.4. Lack of C1's and H_2

While our carbon and O/R balances were found to be in acceptable ranges in most of our conditions, the pathways built from the genome could not account for the stoichiometry we see in end-product production. The extreme example of this is 9078's growth on xylose which appears to be homoacetogenic and as such no C1's appear to be produced. Strain 9078 and DYC both appear to have a fully functioning and typical pentose phosphate pathway (although the number of gene copies differs considerably) and are able to produce glyceraldehyde 3-p for fermentation through glycolysis to pyruvate. However, production of acetate via POR should result in an excess of 1 CO_2 and 2 $ferridoxin_{red}$ equivalents therefore, CO_2 must be consumed or not produced at all as we do not detect any significant amounts under xylose growth when the only major product is acetate.

F. pennivorans does not appear to have the gene complement for a complete Wood-Ljungdahl pathway lacking formate hydrogen lyase (FHL), pyruvate formate lyase (PFL), and carbon monoxide dehydrogenase (CMD). Based on the annotation it should not be able to produce formate for methylate tetrahydrofolate (THF), or uptake CO_2 directly using the Wood-Ljungdahl pathway. This is an apparent contradiction as

the related *Thermotoga lettingae*, which also appears to lacks FHL, PFL, and CMD, upon genome analysis can grow on H_2, CO_2, and elemental sulfur. It is possible that CO_2 uptake might be through another pathway such as the glycine cleavage system, a shared feature among many Thermotogales. Zhang *et al.* (2002) propose the reverse TCA as the mechanism of carbon uptake in *Thermotoga maritima*, our organism does not appear to possess a complete TCA cycle based on annotation. Regardless of the annotation *F. pennivorans* requires some mechanism of converting CO_2 and excess electrons into acetate to explain our C1 to C2 ratio that is not 1:1. Other Thermotogales have been shown to be homo alanine producers using methanol when thiosulfate or elemental sulfate is present (Balk *et al.* 2002). C1 uptake pathways and alanine production have a pertinent connection. Serine is an intermediate of C1 uptake when glycine is methylated. Serine pyruvate ammonia transferase (SPAT), a shared feature of Thermotogales, could utilize serine and pyruvate to create alanine and 2-hydroxypyruvate which could then be cycled back to pyruvate. This would be a relatively straight forward mechanism for homoalanine through C1 metabolism seen in other Thermotogales and causes us to consider the possible role of SPAT in alanine creation under our conditions.

A.6. Conclusion

The *Fervidobacterium* genus, and the order *Thermotogales* in general, remains understudied especially where core metabolism is concerned. The isolation of two unique strains of *F. pennivorans* represents an opportunity to elucidate the inner workings of *Fervidobacterium* via side by side experiments interpreted through the lens of a genomic comparison. Our genetic comparison predicted DYC's inability to grow on gluconate, a feature confirmed via a physiological experiment. Using KEGG pathways and Metecyc we were able to model pathways for major end-products acetate, CO_2, and H_2. The conventional models for alanine and glutamate formation are less than satisfactory due to poor sequence identity of AAT and a missing SDH/FR respectively. The atypical fermentation profile (C1 and C2 ratio that is not 1:1) of *F. pennivorans* under homoacteogenic conditions causes us to look for a C1 uptake pathway in our genome, the complete Wood-Ljungdahl pathway appears to be absent based on annotation. There does appear to be other mechanisms of CO_2 uptake, though we are unable to create a satisfactory pathway.

While *F. pennivorans* does not appear to be an ideal candidate for biofuel production under our conditions, being able to understand and manipulate fermentation in hyperthermophilic organisms is a worthy goal and potential path to create new process of biofuel production. We were unsuccessful in elucidating satisfactory core metabolic pathways in our species, showing that there is still work to be done in regards to genome annotation and physiological experiments.

Appendix E: *C. debilis* and *C. thermocellum* Co-culture Work in Fermenters

The ultimate goal of this work would be a comprehensive omics analysis of the co-culture of *C. debilis* GB1 and *C. thermocellum* in a steady state. Analysis of a co-culture in batch fermenters was initiated. These batch cultures showed a significant decrease in pH within the first 6 hours before any appreciable amount of metabolism from *C. thermocellum* occurred (hydrogen was a clear proxy for *C. thermocellum* metabolism as *C. debilis* does not produce hydrogen). We wanted to ensure we measured the co-culture in steady state so we employed the use of pH-controlled fermenters. We found that the aerobic co-cultures varied significantly in rate of end-product production and the length of time it took for metabolism to begin slowing

down, between 8-14 days. The large differences in aerobic fermenter replicates were likely due to two factors: i) differences in *C. thermocellum* lag time, although we made great efforts to employ consistency and ii) inability to control exact concentration of oxygen in headspace and liquid as aerobic systems were open air.

After several runs we approximated the time of the highest cellulose degradation rate to be ~20 hours anaerobically and ~27 hours aerobically. We decided to sample for omics at this point as we could be confident that *C. thermocellum* was metabolising and synthesising cellulases. We extracted samples for both transcriptomics and proteomics, however we were unsuccessful in getting good quality RNA or total protein. The difficulty in getting good quality RNA and total protein we attributed to i) interference of the solid cellulose substrate on the extraction process, ii) the possibility that cells were not in exponential growth, as the increase in cellulolytic rate between 10-27 hours appeared to be linear and not exponential, and iii) the possibility that a subpopulation of *C. debilis* was utilising dead cell biomass as a substrate secreting proteases, RNases, and DNases.

To alleviate these issues with consistency and omics sample quality several things could be done: i) finer control of the of oxygen concentration in the head space and liquid, ii) sampling for proteomics at earlier time point, perhaps 12-15h, and iii) utilize only as much cellulose substrate as would be degraded on the order of 20 hours to minimize its impact in omics extraction process.

In retrospect we should have taken a more incremental approach, first attempting to measure omics on co-cultures on plates or in batch experiments. Attempting to do omics on the co-culture from the fermenter as a starting point made

it clear we did not have the appropriate understanding of the co-culture dynamics at the time these experiments were done.
