## ABSTRACT

A CONJUGACY PROBLEM IN THE THEORY OF  
FINITE SOLVABLE GROUPS

by

Jack B. Feldman

A finite group  $G$  is solvable if and only if  $G$  has a finite normal series terminating in the identity in which each factor is nilpotent. The most rapidly descending such series is called the lower nilpotent series of  $G$ . For finite solvable  $G$ , the last non-trivial term of the lower nilpotent series is called the lower residual of  $G$  and is denoted by  $L(G)$ . Graham Higman has proved that if  $L(G)$  is abelian then  $L(G)$  is complemented and all complements are conjugate. What happens if  $L(G)$  is not abelian? In this dissertation we give some partial answers to this question.

Let  $G$  be a finite group and  $N$  a normal subgroup of  $G$ . A subgroup  $H$  of  $G$  is a cover of  $N$  if  $G = HN$ ; a minimal cover of  $N$  is called a  $\phi$ -cover. Subgroups  $H$  and  $K$  of  $G$  are  $\pi$ -conjugate,  $\pi$  a set of primes, if the Sylow  $\pi$ -subgroups of  $H$  and  $K$  are conjugate in  $G$ . The group  $G$  is  $p$ -restricted,  $p$  a prime, if the Sylow  $p$ -subgroups of  $G$  have nilpotency class  $\leq 2$ ;  $G$  is  $\pi$ -restricted if  $G$  is  $p$ -restricted for each  $p$  in  $\pi$ .

Let  $G$  be a finite solvable  $\pi$ -restricted group. We obtain necessary and sufficient conditions that all  $\phi$ -covers of  $L(G)$  be  $\pi$ -conjugate. These

necessary and sufficient conditions enable us to prove the following result:

Let  $G$  be a finite solvable group which is  $p$ -restricted for all primes  $p$ .

Then all  $\phi$ -covers of  $L(G)$  are conjugate if and only if they are  $p$ -conjugate for all primes  $p$ .

## ACKNOWLEDGEMENT

I wish to thank my advisor, Professor G. O. Losey, for his guidance and many helpful discussions during the preparation of this thesis.

## Chapter 1

## INTRODUCTION

All groups occurring in this dissertation are assumed to be finite.

Conjugacy Problems

Let  $G$  be a group and  $\mathcal{M}$  a given family of subgroups of  $G$ . The conjugacy problem for the family  $\mathcal{M}$  can be stated as follows :

Are there conditions under which all the members of  $\mathcal{M}$  are conjugate ?

The best known solution of a conjugacy problem is the result due to L. Sylow [12] :

In a finite group  $G$  any two maximal  $p$  - subgroups of  $G$  are conjugate.

More recent results include those of P. Hall [7] :

In a solvable group any two maximal  $\pi$  - subgroups are conjugate.

and of R. Carter [1] :

In a solvable group any two nilpotent self - normalizing subgroups are conjugate.

In the class of solvable groups , these results are special

cases of a general theorem in the theory of formations.

### Solvable Groups

Recall that a group is solvable if it has a normal series in which each factor is abelian. If  $G$  is a solvable group then it has the following properties :

Subgroups and homomorphic images of  $G$  are solvable.

A minimal normal subgroup of  $G$  is an elementary abelian  $p$  - group, for some prime  $p$ .

Proofs of these results may be found in [6], [9] or [11].

Let  $\Pi$  be a set of primes. Denote by  $\Pi'$  the set of all primes not in  $\Pi$ . In particular, if  $p$  is a prime then  $\{p\}'$  will be denoted simply by  $p'$ . An integer  $n$  is called a  $\Pi$  - number if every prime divisor of  $n$  belongs to  $\Pi$ . A group  $G$  is called a  $\Pi$  - group if  $|G|$ , the order of  $G$ , is a  $\Pi$  - number.

A subgroup  $H$  of  $G$  is called a Sylow  $\Pi$  - subgroup ( or a Hall  $\Pi$  - subgroup ) of  $G$  if  $H$  is a  $\Pi$  - group and  $|G : H|$ , the index of  $H$  in  $G$ , is a  $\Pi'$  - number. Denote by  $\text{Syl } \Pi (G)$  the set of all Sylow  $\Pi$  - subgroups of  $G$ . The theorem of P. Hall mentioned in the preceding section can then be stated as :

LEMMA 1.1

If  $G$  is solvable and  $\pi$  a set of primes, then  $\text{Syl } \pi(G)$  is not empty and any two members of  $\text{Syl } \pi(G)$  are conjugate.

Formations

A formation  $\mathcal{F}$  is a class of solvable groups which satisfies the two conditions :

- (1) If  $G \in \mathcal{F}$  and  $N \triangleleft G$  then  $G/N \in \mathcal{F}$
- (2) If  $M, N \triangleleft G$  and  $G/M, G/N \in \mathcal{F}$   
then  $G/M \cap N \in \mathcal{F}$

A formation  $\mathcal{F}$  is said to be saturated if it also satisfies the condition :

- (3) If  $G/\phi(G) \in \mathcal{F}$  then  $G \in \mathcal{F}$

where  $\phi(G)$  denotes the Frattini subgroup.

If  $\mathcal{F}$  is a formation and  $G$  a group then the  $\mathcal{F}$ -residual of  $G$  is defined to be the subgroup

$$\mathcal{F}(G) = \bigcap \{ M \triangleleft G \mid G/M \in \mathcal{F} \}$$

From (2) it follows that if  $N$  is a normal subgroup of  $G$ , then  $G/N \in \mathcal{F}$  if and only if  $\mathcal{F}(G)$  is contained in  $N$ .

Let  $E$  be a subgroup of the group  $G$ . Then  $E$  is called an  $\mathcal{F}$ -covering subgroup of  $G$  for the formation  $\mathcal{F}$  if

- (1)  $E \in \mathcal{F}$
- (2)  $E \leq H \leq G$  implies  $H = \mathcal{F}(H) E$

The conjugacy results given in the opening section of this chapter can all be obtained, for a solvable group  $G$ , from

the following theorem of Gaschutz [5] , by a suitable choice of the formation  $\mathcal{F}$  .

LEMMA 1.2

Let  $\mathcal{F}$  be a saturated formation and  $G$  a solvable group. Then  $G$  has  $\mathcal{F}$  - covering subgroups, and they are all conjugate.

For example, let  $\mathcal{N}$  denote the class of all nilpotent groups. It follows from the elementary properties of nilpotent groups that  $\mathcal{N}$  is a formation ( see [9] ). In [13] Wielandt has proved that a group  $G$  is nilpotent if  $G/\Phi(G)$  is nilpotent. Thus we have the following :

LEMMA 1.3

The class  $\mathcal{N}$  of all nilpotent groups is a saturated formation.

The  $\mathcal{N}$  - covering subgroups of a solvable group  $G$  are the nilpotent self - normalizing subgroups of  $G$  ( see Carter [1] , Gaschutz [5] ).

Nilpotent Series and Nilpotent Length

A descending sequence of subgroups

$$G = G_0 \triangleright G_1 \triangleright G_2 \triangleright \dots \triangleright G_i \triangleright \dots$$

is called a descending nilpotent series for  $G$  if each factor  $G_i/G_{i+1}$  is nilpotent. It is immediate that  $G$  has a descending nilpotent series terminating with  $G_n = 1$  , for

some  $n$ , if and only if  $G$  is solvable. For any group  $G$  we may define a canonical descending nilpotent series as follows :

$$R_0 = G, \quad R_{i+1} = \mathcal{N}(R_i)$$

where  $\mathcal{N}(R_i)$  is the  $\mathcal{N}$ -residual of  $R_i$ . The series

$$G = R_0 \supseteq R_1 \supseteq R_2 \supseteq \dots \supseteq R_i \supseteq \dots$$

of characteristic subgroups of  $G$  is the most rapidly descending nilpotent series for  $G$  in the following sense :

LEMMA 1.4

For any descending nilpotent series

$$G = G_0 \triangleright G_1 \triangleright G_2 \triangleright \dots \triangleright G_i \triangleright \dots$$

we have  $R_i \leq G_i$  for all  $i$ .

Proof. The lemma is true for  $i = 0$ .

Assume  $R_j \leq G_j$  and apply induction.

$$G_j/G_{j+1} \supseteq R_j G_{j+1}/G_{j+1} \cong R_j/R_j \cap G_{j+1}$$

Since  $G_j/G_{j+1} \in \mathcal{N}$  we also have  $R_j/R_j \cap G_{j+1} \in \mathcal{N}$

so  $R_{j+1} \leq R_j \cap G_{j+1}$ . Hence  $R_{j+1} \leq G_{j+1}$ .

The series  $G = R_0 \supseteq R_1 \supseteq R_2 \supseteq \dots$

will be called the lower nilpotent series for  $G$ . If  $G$  is solvable then this series terminates in the identity. The least integer  $n$  such that  $R_n = 1$ , for the solvable group  $G$ ,

is called the nilpotent length of  $G$  and is denoted by  $m(G)$ .

We define  $(i)\mathcal{N}$  to be the class of all solvable groups  $G$  such that  $m(G) \leq i$ . In [5] it is proved that

LEMMA 1.5

$(i)\mathcal{N}$  is a saturated formation.

Existence and Conjugacy of Complements of  $L(G)$

If  $G$  is solvable and  $m(G) = n > 0$  then  $R_{n-1}$  will be called the lower residual of  $G$  and will be denoted by  $L(G)$ .

Let  $G$  be a solvable group with  $m(G) = n$ .

Let  $\mathcal{F} = (n-1)\mathcal{N}$  and let  $X = \mathcal{F}(G)$ . Since  $G/L(G) \in \mathcal{F}$  it follows that  $X \leq L(G)$ . But  $G$  has a descending nilpotent series which passes through  $X$ . Hence  $L(G) \leq X$  by lemma 4. Therefore  $L(G) = X = \mathcal{F}(G)$ .

In 1955 Schenkman [10] proved

LEMMA 1.6

Let  $G$  be solvable. If  $\mathcal{N}(G)$  is abelian then it is complemented in  $G$  and any two complements are conjugate.

In 1956 G. Higman [8] extended this to

LEMMA 1.7

Let  $G$  be solvable. If  $L(G)$  is abelian then it is complemented in  $G$  and any two complements are conjugate.

This was generalized by Carter and Hawkes [3] :

LEMMA 1.8

Let  $\mathcal{F}$  be a saturated formation, and  $G$  a solvable group. If  $\mathcal{F}(G)$  is abelian then it is complemented in  $G$ , and the complements are the  $\mathcal{F}$ -covering subgroups of  $G$ . Thus any two complements are conjugate (by lemma 2).

Statement of the Problem and Results

Let  $G$  be a group and  $N$  a normal subgroup of  $G$ . A subgroup  $H$  of  $G$  is called a cover of  $N$  in  $G$  if  $G = NH$ . We call  $H$  a minimal cover of  $N$  if no proper subgroup of  $H$  is a cover of  $N$ .

Let  $M$  and  $N$  be subgroups of a solvable group  $G$ . Let  $\Pi$  be a set of primes and let  $P \in \text{Syl } \Pi(M)$ , and  $Q \in \text{Syl } \Pi(N)$ . We say that  $M$  and  $N$  are  $\Pi$ -conjugate in  $G$  if and only if  $P$  and  $Q$  are conjugate in  $G$ . This definition is independent of the choice of  $P$  and  $Q$ , by lemma 1.

The problem to be investigated in this dissertation is the following :

Are there conditions under which all minimal covers of  $L(G)$  will be  $\Pi$ -conjugate in  $G$  for a given set of primes  $\Pi$  ?

The results we obtain are based on the concept of a group which is  $\Pi$ -restricted. Let  $p$  be a prime. We say that  $G$  is  $p$ -restricted if the nilpotency class of a Sylow  $p$ -subgroup of  $G$  is not greater than two. If  $\Pi$  is a set of primes

then  $G$  is called  $\Pi$ -restricted if  $G$  is  $p$ -restricted for each prime  $p$  in  $\Pi$ .

The problem will now be stated in its specific form. Let  $\Pi$  be a set of primes and let  $G$  be a  $\Pi$ -restricted solvable group. If  $Y$  is a minimal cover of  $L(G)$ , under what conditions will  $Y$  be  $\Pi$ -conjugate to all other minimal covers of  $L(G)$ ? In chapter 2 we describe conditions that are both necessary and sufficient for  $Y$  to have this property. The proofs are given in chapter 4.

The conditions for the  $\Pi$ -conjugacy of all minimal covers of  $L(G)$  as given in chapter 2 require some results from the theory of  $p'$ -groups of automorphisms of abelian  $p$ -groups. However, it is possible to give a brief summary of these conditions without reference to this material.

Let  $G$  be a solvable group,  $X = L(G)$  and  $Y$  a minimal cover of  $X$  in  $G$ . Let  $p$  be a prime. A  $p$ -mapping from  $X$  to  $Y$  is a triple  $(\theta, N, K/L)$  such that

- (1)  $N$  is a normal  $p$ -subgroup of  $G$  which is contained in  $X'$  but not contained in  $Y$ , and  $N/\phi(N)$  is a chief factor of  $G$
- (2)  $K/L$  is a complemented  $p$ -chief factor of  $Y$
- (3)  $\theta : N \longrightarrow K/L$  is a  $Y$ -homomorphism of  $N$  onto  $K/L$ , that is, for all elements  $g \in N, y \in Y$  we have

$$\theta(g^y) = \theta(g)^y$$

If  $\Pi$  is a set of primes and  $G$  is  $\Pi$ -restricted, we define a  $\Pi$ -mapping from  $X$  to  $Y$  as a  $p$ -mapping from  $X$  to  $Y$  for some prime  $p$  in  $\Pi$ . The main result of this dissertation can be stated as follows :

Theorem

Let  $\Pi$  be a set of primes and let  $G$  be a  $\Pi$ -restricted solvable group. Set  $X = L(G)$  and let  $Y$  denote some fixed minimal cover of  $X$  in  $G$ . Then all minimal covers of  $X$  in  $G$  are  $\Pi$ -conjugate if and only if there do not exist any  $\Pi$ -mappings from  $X$  to  $Y$ .

There is an interesting consequence of this theorem :

Corollary

Let  $G$  be solvable and  $p$ -restricted for all primes  $p$ . Then all minimal covers of  $L(G)$  are conjugate in  $G$  if and only if they are all  $p$ -conjugate for all primes  $p$ .

Note : The curved brackets  $\{ \quad \}$  will be used to denote sets , and the straight line brackets  $\langle \quad \rangle$  will be used to denote subgroups.

Notation and Terminology

The capitals  $A, B, C, \dots$  will always denote groups and subgroups.

## Chapter 2

CONDITIONS FOR  $\Pi$ -CONJUGACY

The material in this chapter is applied to give an alternative definition of a  $p$ -mapping. This definition makes direct use of the fact that the group  $G$  is  $p$ -restricted.

Abelian  $p$ -groups Acted on by  $p'$ -groups

Let  $G$  and  $A$  be groups. We define an action of  $A$  on  $G$  as a homomorphism  $\sigma$  of  $A$  into the automorphism group of  $G$ .

$$\sigma : A \longrightarrow \text{Aut}(G)$$

Let  $\alpha \in A$  and  $g \in G$ . Then we write

$$g^\alpha \equiv g^{\sigma(\alpha)}$$

A subgroup  $H$  of  $G$  is called  $A$ -invariant if  $H^\alpha = H$  for all elements  $\alpha \in A$ . If  $N$  is a normal  $A$ -invariant subgroup of  $G$  then  $A$  also acts on  $G/N$  by :

$$(gN)^\alpha = g^\alpha N$$

If  $A$  acts on groups  $G$  and  $H$ , then a homomorphism

$$\theta : G \longrightarrow H$$

is an  $A$ -homomorphism if for all  $g \in G$ ,  $\alpha \in A$

$$(g^\alpha)^\theta = (g^\theta)^\alpha$$

In this case we write  $\Theta : G \xrightarrow[A]{} H$

An isomorphism  $\Theta : G \longrightarrow H$  which is an  $A$  - homomorphism will be called an  $A$  - isomorphism. If  $G$  and  $H$  are  $A$  - isomorphic we will write  $G \underset{A}{\cong} H$ .

The group  $G$  is  $A$  - indecomposable if  $G$  cannot be written as a direct product of two nontrivial  $A$  - invariant subgroups. The group  $G$  is  $A$  - basic if it cannot be written as the direct product of two nontrivial subgroups, at least one of which is  $A$  - invariant.

We are interested here in the action of a  $p'$  - group  $A$  on an abelian  $p$  - group  $P$ . Throughout the remainder of this section  $A$  and  $P$  will denote such groups.

LEMMA 2.1 [6, p. 69]

If  $E$  is an  $A$  - invariant direct factor of  $P$  then

$$P = E \times F$$

where  $F$  is also  $A$  - invariant.

This lemma states that, with the fixed hypothesis that  $A$  is a  $p'$  - group and  $P$  an abelian  $p$  - group, the concepts of  $A$  - indecomposable and  $A$  - basic are equivalent.

COROLLARY 2.2

It is possible to write  $P$  as the direct product of subgroups, each of which is  $A$  - basic.

LEMMA 2.3 [6, p. 176]

If  $P$  is  $A$ -basic then  $P$  is homocyclic, that is, a direct product of cyclic subgroups all of the same order.

We define two  $A$ -invariant subgroups of  $P$  :

$$C_P(A) = \{g \in P \mid g^\alpha = g \text{ for all } \alpha \in A\}$$

$$[P, A] = \langle g^{-1} g^\alpha \mid g \in P, \alpha \in A \rangle$$

LEMMA 2.4 [6, p. 177]

$$P = C_P(A) \times [P, A]$$

We define a characteristic, and hence  $A$ -invariant elementary abelian subgroup of  $P$  :

$$\Omega(P) = \{g \in P \mid g^p = 1\}$$

LEMMA 2.5

If  $P$  is  $A$ -basic then  $\Omega(P)$  is also  $A$ -basic.

Proof. Let  $P$  be  $A$ -basic. Then  $P$  is homocyclic of exponent  $p^n$ , for some integer  $n$ . If  $P$  has exponent  $p$  then  $P = \Omega(P)$ . Thus we may assume  $P$  is not elementary abelian. Suppose  $\Omega(P)$  is not  $A$ -basic. Then

$$\Omega(P) = M \times N$$

where  $M$  and  $N$  are nontrivial and  $A$ -invariant. It can be assumed that  $N$  is  $A$ -basic.

Set  $\bar{P} = P/N$ . Since  $P$  is homocyclic and not elementary abelian,  $N$  is contained in  $\Phi(P)$ .

This implies that a minimal set of generators of  $P$  has the same number of elements as a minimal set of generators of  $\overline{P}$ . To state this in simple form, we say that  $P$  and  $\overline{P}$  have the same number of generators. The generators of  $P$  are of order  $p^n$  and  $N$  is nontrivial, so some of the generators of  $\overline{P}$  will be of order  $p^{n-1}$ . Clearly  $P$  and  $\Omega(P)$  have the same number of generators. But  $M$  is nontrivial, so  $N$  has less generators than  $P$ . Therefore  $\overline{P}$  will have some generators of order  $p^n$ . Thus  $\overline{P}$  is not homocyclic.

Since  $N$  is  $A$ -invariant,  $\overline{P}$  is acted on by  $A$ . But  $\overline{P}$  cannot be  $A$ -basic since it is not homocyclic. Any direct factor of  $\overline{P}$  which is  $A$ -basic will be of exponent either  $p^n$  or  $p^{n-1}$ . Thus we have

$$\overline{P} = \overline{K} \times \overline{L}$$

$\overline{K}$  is  $A$ -invariant of exponent  $p^n$

$\overline{L}$  is  $A$ -invariant of exponent  $p^{n-1}$

Let  $K, L$  be the inverse images in  $P$  of  $\overline{K}$  and  $\overline{L}$ . Since  $K$  is  $A$ -invariant and  $\phi(K) \text{ char } K$ , it follows that  $\phi(K)$  is  $A$ -invariant. Thus  $\phi(K) \cap N$  is also  $A$ -invariant. Since  $N$  is  $A$ -basic and elementary abelian, we must have either  $\phi(K) \cap N = 1$  or  $N \leq \phi(K)$ . But if  $N \leq \phi(K)$  then  $K$  and  $\overline{K}$  have the same number of generators, so  $\overline{K}$  cannot be homocyclic of exponent  $p^n$ . Therefore  $\phi(K) \cap N = 1$  and  $N$  is a direct factor of  $K$ . By lemma 1,  $K = N \times F$  where  $F$  is  $A$ -invariant.

Now  $P = FL$  and  $|P| = |F||L|$ . Thus  $F \cap L = 1$ . We conclude that  $P = F \times L$  since  $P$  is abelian. Since  $F$  and  $L$  are  $A$ -invariant,  $P$  is not  $A$ -basic, which is a contradiction.

LEMMA 2.6

If  $P$  is homocyclic then  $P/\Phi(P) \cong_{\mathbb{A}} \Omega(P)$

Proof. Let  $P$  have exponent  $p^n$ . We can define a homomorphism  $\theta: P \longrightarrow \Omega(P)$  by the equation

$$g^\theta = g^{p^{n-1}} \quad \text{for all } g \in P$$

This is clearly an  $A$ -homomorphism of  $P$  onto  $\Omega(P)$ . The kernel consists of all elements of order not greater than  $p^{n-1}$ , that is, the Frattini subgroup  $\Phi(P)$ . The result now follows from the basic homomorphism theorems for groups with operators.

$\Pi$ -primary and  $\Pi$ -secondary Minimal Covers of  $L(G)$ .

Let  $\Pi$  be a set of primes. Throughout this section  $G$  will be a solvable  $\Pi$ -restricted group. Set  $X = L(G)$  and let  $Y$  be a fixed minimal cover of  $X$  in  $G$ .

Let  $p$  be some prime in  $\Pi$ . Since  $X$  is nilpotent it has a unique Sylow  $p$ -subgroup. Let  $M$  denote this subgroup. We will write  $M = \text{Syl}_p(X)$  to indicate that it is unique.

We have  $M \text{ char } X \text{ char } G$ . Therefore  $M \text{ char } G$ .  
 Similarly  $M' \text{ char } G$ . Since  $p$  belongs to  $\Pi$ ,  $G$  is  
 $p$ -restricted.

LEMMA 2.7

Let  $P$  be a Sylow  $p$ -subgroup of  $G$ . Then  $M'$  is  
 contained in  $Z(P)$ . Hence  $P$  is contained in  $C_G(M')$ .

Proof. Since  $M$  is normal in  $G$ ,  $M$  is contained  
 in  $P$ . This implies  $M'$  is contained in  $P'$ . But  $G$  is  
 $p$ -restricted so  $P$  has class two at most. Hence  $P'$  is  
 contained in  $Z(P)$  and  $M'$  is also.

Since  $M'$  is normal in  $G$ , we can say that  $G$  induces  
 a group of automorphisms on  $M'$  by conjugation, or by our  
 previous terminology, we can say that  $G$  has an action on  $M'$   
 which is defined by conjugation in  $G$ . An element  $g$  of  $G$   
 induces the identity automorphism on  $M'$  if and only if  $g$  is  
 contained in  $C_G(M')$ . Let  $A_G(M')$  denote the group of  
 automorphisms induced on  $M'$  by  $G$ . This is the image of  $G$   
 in the homomorphism of  $G$  into  $\text{Aut}(M')$  which defines the  
 action of  $G$  on  $M'$ . Now  $C_G(M')$  is a normal subgroup of  $G$   
 since  $M'$  is normal in  $G$ . Thus we have the isomorphism

$$A_G(M') \cong G/C_G(M')$$

By lemma 7,  $P$  is contained in  $C_G(M')$ , hence  $A_G(M')$   
 is a  $p'$ -group.

LEMMA 2.8

$M'$  is a characteristic abelian  $p$ -subgroup of  $G$ , and  $G$  induces a  $p'$ -group of automorphisms on  $M'$ .

Since  $M'$  is contained in  $Z(M)$  and  $X$  is nilpotent, it follows that  $M'$  is contained in  $Z(X)$ . Thus  $X$  is contained in  $C_G(M')$ . It then follows from the fact that  $G = XY$  that  $Y$  induces the same group of automorphisms on  $M'$  as  $G$  does.

COROLLARY 2.9

$Y$  induces a  $p'$ -group of automorphisms on  $M'$ . Furthermore if  $N$  is a subgroup of  $M'$ , then  $N$  is normal in  $G$  if and only if  $N$  is  $Y$ -invariant.

We are now in a position to give a new definition of the concept of a  $p$ -mapping. Let  $G$  be a solvable  $p$ -restricted group. Set  $X = L(G)$  and let  $Y$  be a minimal cover of  $X$  in  $G$ . We define a  $p$ -mapping from  $X$  to  $Y$  to be a triple  $(\theta, N, K/L)$  such that

- (1)  $N$  is a normal  $p$ -subgroup of  $G$  which is contained in  $X'$  but not contained in  $Y$ , and  $N$  is  $Y$ -basic
- (2)  $K/L$  is a complemented  $p$ -chief factor of  $Y$
- (3)  $\theta : N \longrightarrow K/L$  is a  $Y$ -homomorphism of  $N$  onto  $K/L$ .

Generally we will simply say that

$$\Theta: N \xrightarrow{Y} K/L$$

is a  $p$ -mapping.

To establish the equivalence of the two definitions we show that the conditions on  $N$  are the same :

- (a)  $N$  is a normal  $p$ -subgroup of  $G$  which is contained in  $X'$ , and  $N/\Phi(N)$  is a chief factor of  $G$
- (b)  $N$  is a normal  $p$ -subgroup of  $G$  which is contained in  $X'$ , and  $N$  is  $Y$ -basic

In both cases  $Y$  induces a  $p'$ -group of automorphisms on  $N$ , and  $N$  is an abelian  $p$ -group.

Assume (a) holds. By corollary 2,  $N$  is a direct product of  $Y$ -basic subgroups. Each  $Y$ -basic direct factor of  $N$  is normal in  $G$ , by corollary 9. Since  $N/\Phi(N)$  is a chief factor of  $G$ ,  $N$  must be  $Y$ -basic, so (b) holds.

Assume (b) holds. Since  $\Phi(N)$  is characteristic in  $N$ , it is normal in  $G$ . By lemma 5,  $\Omega(N)$  is  $Y$ -basic, so from lemma 6 we get that  $N/\Phi(N)$  is also  $Y$ -basic. Since  $N/\Phi(N)$  is elementary abelian, it must be a chief factor of  $G$ . Thus (a) holds.

Let  $G$  be a  $\Pi$ -restricted solvable group. As in chapter 1, a  $\Pi$ -mapping is defined to be a  $p$ -mapping for some prime  $p$  in  $\Pi$ . We say that  $Y$  is a  $\Pi$ -primary minimal cover of  $X$  if there do not exist any  $\Pi$ -mappings from  $X$  to  $Y$ . If there do exist  $\Pi$ -mappings, then
